Bees are subject to three principal diseases, namely, *dysentery*, distinguished by the black colour and offensive odour of their excrement, and supposed to be contagious; a nervous affection, called by some writers *vertigo*, supposed to be produced by the honey of some narcotic plant; and a kind of *debility*, shewing itself by a degree of langour, and a swelling and yellow colour of the head and tips of the antennæ. The two former of these diseases are supposed to be incurable; but the last is said to be removed by giving the bees Spanish wine.

Duration of life.—Bees so seldom die a natural death, that it is not easy to determine the period of their existence. Most writers however agree, that it seldom exceeds two years among the workers, though the term of life assigned to the queen is somewhat longer.

Part II. Management of Bees.

The cultivation of bees is extremely profitable, and merits much more attention than it generally receives. It is still capable of much improvement, though the labours of modern observers and cultivators have afforded many valuable hints. There are two great objects which the proprietor should keep in view—to enable his bees to collect as much wax and honey as possible, and to encourage their propagation and increase. To attain these objects he must attend to the *situation* of the *apiary*;—the *structure* of the *hives*;—the *management* of *swarms*;—the the mode of *removing the combs*;—and the *protection* of the bees during winter.

Apiary.—The best situation for bee-hives is a garden, well stocked with flowers and flowering shrubs, or low standard fruit trees, and in the neighbourhood of pastures bordered with heath, furze (whin,) or broom. The contiguity of high trees should be avoided; but it is very desirable that a small rivulet or stream of water should be near, as bees are fond of sipping water, even though it be muddy. The hives should be arranged along a border, a few feet from a wall not too high, that has a moderately warm exposure, somewhat between south and east; and they should be placed separately, each on a stout wooden table, with a narrow projecting part in front, supported on a strong wooden post, about two feet from the ground. Thus placed, the hives are sheltered from inclement blasts, while they are not too much exposed to the heat of the sun reflected from the wall, and being thus elevated on a single support, are not so liable to the incursions of large crawling or climbing enemies. The table should be rather larger than the bottom of the hive, and should be a little raised in the middle to allow the rain to run off. There must be a sufficient space between the hives, to prevent disputes among the neighbouring settlements; and for this purpose an interval of at least three or four feet is requisite. No tall plants or rank weeds should be suffered to grow round the hives, as they encourage and harbour insects; but the ground below the tables should be spread with gravel, or sprinkled with coal ashes. The table on which the hives are placed should be swept clean three or four times a-year, especially in the beginning of spring and conclusion of the honey season.

It is of some consequence to select for the garden such flowers as are most productive of wholesome honey, and to keep up a succession of these from spring to autumn. Among the most profitable summer plants mignionette holds a high rank, and many of the pot herbs, as thyme and marjoram, are much frequented by the bees.

Transporting bees.—In some countries, particularly Egypt and Asia Minor, the proprietors of bees transport their hives from one place to another, for the sake of providing them a more abundant supply of flowers. The practice has been followed to a certain extent in France, and even in Britain; but it is not probable that in this country it will ever become general or sufficiently advantageous to compensate the trouble and expense attending it. In conveying the hives from one situation to another, it is proper to tie each separately in a cloth or sheet, and arrange them on hand-barrows, or in a well hung spring-cart, or what is still better, where water-carriage is admissible, in a boat; travelling by night, and resting by day, to let the bees feed, till they reach their place of destination. Great care should be taken not to agitate the hives, for fear of loosening and separating the combs.

Structure of hives.—The hives in which bees are kept, may be made either of straw or wood. The former are warmer, the latter more convenient, especially for the purpose of observation. The common bee-hive, or *scape* as it is sometimes called, is nearly of a spherical figure, with a segment cut off below, or sometimes like a bell; and though well suited to retain the combs, is very ill adapted to the economical purpose of abstracting them without destroying the bees. A much better form is that of a cylinder, about nine inches deep, and twelve in diameter, open at both ends, but having a circular frame, with as many cross bars of wood as there are intended to be combs in the head, to close it in at the top. These hives are so constructed as to fit over each other, so as to increase the internal cavity, and the uppermost is covered with a hemispherical lid nicely adjusted, fastened with packthread, and the junctions secured with putty or mortar. Two of these cylinders adapted to each other, and the entrance hole of the upper closed, form a very proper habitation for a new swarm, and the lower cylinder, when full, may be exchanged for an empty one, in the mode to be presently described.

We have seen eight-sided wooden boxes, having several slits at top capable of being closed by a sliding board, and a pane of glass, with a sliding shutter in one side, for the purpose of observing the bees at work, employed as hives; and if not made too large they answer very well.

But of all the wooden hives of which we have seen any account, we prefer that contrived by M. Huber, and described by him in his "New Observations on Bees." This is called the *leaf* or *book-hive*, from its being composed of thin compartments fitted laterally to each other, and opening in the manner of the leaves of a book. The component *leaves* of this hive form each a frame of wood twelve inches long by ten broad, and about one inch thick by fifteen lines from side to side. Those intended to form the interior of the hive are open at the sides, but the two that are to form the outer lateral parts are closed by a stout board. They must all be nicely adapted to each other, and fastened together by hinges screwed to the edge, so as easily to be removed or replaced. Each compartment is intended for holding one comb, and Huber recommends placing a small piece of comb at the upper bar to direct the operation of the bees. Each has a moderate-sized hole in the front edge near the bottom, for the passage of the bees in and out. It is convenient to have them so adapted that the whole may open in the middle for the purpose of introducing a swarm, or examining the interior of the settlement. By the addition or removal of such divisions, the size of the hive may be regulated according to circumstances. The combined panes are covered at the top with a sloping wooden roof to throw off the rain; and they are kept firmly together by outside bars secured by pins.

The description here given of Huber's hive differs in some respects from that given by Mr Huish; and it appears that there are at least two modifications of it, though the general principle of construction is the same.

These hives are attended with many advantages. In particular they admit of inspection into every part, for the purpose either of curious observation, or of ascertaining the state of the colony, or the situation of the queen; they tend to increase the quantity of wax and honey produced, and they allow the greatest facility in removing any part of the combs without destroying, or materially disturbing the bees. The only inconvenience to which they seem liable, is, that they are apt to expose the combs and bees to injuries from the weather; an objection which may be obviated by making them of well-seasoned wood, and taking care that the junctures are extremely close.

The hive recommended by Huish, which is nearly the same with the Greek hives described by travellers to mount Hymettus, of which it is not easy to conceive that the author was ignorant, is of straw, shaped like a flower-pot, and made open at both ends. The smaller end forms its bottom; and upon the other are laid, at equal distances, eight or nine long pieces of wood, about three inches broad and half an inch thick, and secured on the edge so as to be easily lifted, but not to slide backwards and forwards. Over these cross bars is laid a piece of network; over this a circular board, having six holes

Management.

above the insterstices of the bars, fitted with perforated tin-plates, to let out the heated steam of the hive; and the whole is covered with a convex straw top, hanging a little over the edge, and firmly cemented to the body of the hive. The combs being attached to the cross bars, are, from the shape of the hive, easily lifted out, and fresh bars placed for the bees to construct new combs; so that this hive has the advantage both of simplicity of construction and facility of management.

Sometimes several hives are placed above each other like the stories of a house, constituting what is called the *storyfying system.* This system is by some supposed to have many advantages; as that the bees have most room, and have therefore not so much inducement to swarm; and that being more numerous, they preserve a higher temperature in the hive and breed earlier; while, from the quantity of combs, they are not exposed to famine. We consider some of these advantages as imaginary, and advise this system not to be carried too far.

Management of swarms.—When it is expected that a hive will swarm, strict attention must be paid to watch the exit of the bees and prevent their escape. Swarming takes place in the early part of the day, and in fair weather, so that the trouble of watching is comparatively small. When the swarm has fairly collected, and alighted for its first rest, preparations should immediately be made for securing the bees before they take their second flight. For this purpose, a clean hive is to be provided; and if it be made of straw, two cross pieces of wood should be placed within it, about the middle, so as to assist in supporting the combs. It is usual in this country to wash the inside of the hive with sugar and water, and rub it well with green leaves, or a brush to rub off the loose ends of straw that project from the sides. Taking the hive, thus prepared, in one hand, and being defended by coarse worsted gloves, gaiters on his legs, and a linen dress, with a mask of wire-cloth over the hat and face, and tied round the body, the person who is to *hive the swarm*, as it is called, holds the hive immediately below the assembled group of bees, and giving the bough or bush on which they have settled, a smart shake generally succeeds in lodging most of them within the hive. He then cautiously turns down the hive upon a board or table, covered with a cloth, and leaves it in the same spot till towards the evening, when it is carried to the place where it is to stand. It is sometimes necessary to detach the bees, by means of a goose's wing, which forms the best brush on these occasions; and in all cases where the queen can be found, and secured within the hive, the bees are easily lodged in their proper habitation.

There are certain precautions to be observed by those who undertake the hiving of bees, or indeed any operation in which the bees are likely to be irritated. He should be dressed in light-coloured clothes, should avoid breathing on the bees, and should there arise great agitation, and the bees appear much irritated, it will be proper to keep them off by the smoke of burnt linen, paper, or dry cow-dung, thrown on live coals in a small chaffer or pan, with a perforated cover and a short handle, which the operator is to carry about with him.

It is of some consequence, especially in the later swarms, to ascertain the size of the swarm, that it may not prove too weak for surviving the winter. The usual method of doing this is by weighing the hive. If the weight of the bees, exclusive of that of the hive, do not amount to 4lbs. avoirdupois, it is considered as a weak swarm; and in this case it is recommended to put two swarms together. To do this, so as to secure the tranquillity of the bees, it is necessary to take away the queen belonging to one of the swarms.

Artificial swarms.—It is not a difficult matter, and may sometimes be desirable, to separate the bees in a hive into distinct colonies, without waiting for their swarming. This is called producing artificial swarms; and is easily effected by means of Huber's leaf-hive, in the following manner. The usual compound hive, formed of ten or twelve compartments, is cautiously divided in the middle, and two leaves, each closed on one side, are gently slid between the two halves, so that their open parts shall be next the interior of each half. Search must now be made to find which half contains the queen, and should she be found in that which has most eggs or worms, it will be necessary to transfer her to the other half, in order to give the bees in the former division the best chance of rearing a new queen from the brood there lodged. Then the two half hives are to be brought together, and united, by tying a small cord firmly round them, taking care to place them in the same position as the whole hive had formerly occupied. The former opening in front of the hive is to be closed, and another opened in each of the divisions, as far as possible from each other, only that it would be better to keep the division that is without a queen so far closed as not to allow the bees to pass while it admits a supply of fresh air. The bees soon repair the loss of their queen, and in about ten or fifteen days the hive may be finally separated.

We have heard of an ingenious way of compelling bees to swarm, when they appear rather tardy in doing so. This consists in removing the hive, which has shewn the usual indications of swarming to another part of the garden; and we are assured that in a short time the swarm has issued forth, and alighted on the table that supported the old hive, so that it was easily collected in a fresh hive and transferred to a separate stand, while the parent settlement was brought back to its original seat.

Abstraction of combs.—It is well known that the usual method of taking possession of the spoils collected by the bees, is to place the hive over a hole dug in the earth, introducing below it lighted brimstone, and closing the mouth of the hive so as to suffocate the unfortunate insects. This is not only cruel, but it is very impolitic and extravagant, and it tends to injure the flavour of the honey. With the common spherical hives it is indeed not easy to remove the combs in any other way, but it may be done with the cylindrical straw-hives already described, and still more easily by employing the leaf-hives of Huber. The best time for taking the combs is when the hives have attained their greatest weight;

Management.

to ascertain which, they should in autumn be frequently inspected, and raised so as to be weighed by hand. The heaviest hives, and those containing the freshest combs, are to be selected; and when the straw-cylinders are employed, the bees are to be driven towards the upper division, by tapping gently for sometime upon the lower, after loosening any cement by which the junction had been secured. Then a long and pretty sharp knife, or what is better, a clean wire, with two handles, is to be passed between the lower division and that immediately above it. The former is then to be removed to a distance; and if the season be not too far advanced, or if the bees appear to require room, an empty hive is placed below and the juncture secured as before. If the upper compartment be of small size, it will be proper to place an *eek*, or shallow cylinder, below; as, when the combs are cut close to the bottom, and consequently rest upon the table, if no addition be made, the circulation of air through the hive is materially obstructed, and the bees often perish before they can open proper communications between the combs. It is necessary, therefore, when no *eck* is added, to cut out a portion from the lower part of each comb to ensure communication and ventilation. With the hive of Huber all that is necessary is to select those divisions which contain the richest combs, and cautiously separate them from the rest, substituting empty ones in their room; and this may be done at any part of the season. If the combs abstracted contain many cells filled with young bees, these portions may be cut out and fastened within the empty divisions.

In taking away the honey and wax without destroying the bees, it is proper to leave at least what may be necessary to support them through the winter, unless it be so early in the season that they have time to collect a fresh stock. The quantity of honey and wax that a hive of bees can collect during one season varies considerably, according to their numbers and the abundance of flowers near them. An ordinary hive will yield from 50 to 80 pounds of honey, and two or three of wax; but when the bees are allowed sufficient space, and the season productive, more than double these quantities has been produced.

Separation of the honey.—More nicety is required in the separation of the honey, and management of the wax, than is commonly supposed. The combs should first be carefully examined; the young brood, bee-bread, and any decayed or much discoloured parts cut away, and the comb containing honey sorted according to its quality. Then, with a sharp knife, the coat of wax that closes the cells is to be pared off, the comb cut in pieces, and laid on coarse haircloth sieves to drain. The honey procured in this way, without heat or pressure, is the purest, and is called *Virgin honey*, and should be kept by itself. Gentle pressure, assisted, if necessary, by moderate heat, procures other honey, which is generally mixed with a little wax. From this and other impurities it may be freed, by melting it in a vessel placed in a pan of boiling water, scumming off what rises to the surface, and pouring off the clear melted honey from the sediment.

When all the honey has been separated, the wax is to be melted with water, and strained through a cloth sufficiently coarse to admit the wax to pass through without the impurities with which it is contaminated. It is then left to cool on the surface of the water, again melted by itself with a gentle heat, and poured into proper dishes to cool into those thick round cakes in which it is usually bought.

Uses of honey and wax.—Besides being very generally employed as an article of diet, honey is much used in medicine, in making those acid syrups called oxymels, and as a grateful and laxative emollient; though, from its often exciting griping pains in the stomach and bowels, its use has of late been much superseded by that of sugar. It is a common external application among country people, in cases of burns and inflammation of the eyes, in which it has the valuable property of *doing no harm*. From this substance, too, is prepared that fermented liquor called *mead* or *metheglin*.

Wax is a still more valuable article than honey, but is produced in much less abundance. So little equal is the produce of wax in this country to its consumption, that it is asserted by Huish that nearly L.80,000 is annually paid by Britain for wax imported from abroad. Most of this large quantity comes from Germany, and is collected and shipped chiefly at the port of Dantzic. Much wax is used in the practice of surgery, as it forms a principal ingredient in most ointments, cerates, and plasters; but the greatest consumption of this product is in the manufacture of candles, for which purpose it is previously bleached. Wax is now very commonly employed, melted and mixed with oil of turpentine, for giving a polish to mahogany furniture. The best wax is of a light yellow colour, a fragrant smell, and rather brittle than soft. When melted it should be transparent, and deposit very little sediment.

Preservation of bees.—The preservation of bees through the winter, and the protection of them from the various enemies and casualties to which they are exposed, form an important part of their management. When the state of the hives has been properly examined at the end of autumn, and such portions of the honey and wax have been taken away as it is thought the bees can spare, the space between the lower edge of the hive and the table on which it stands should be filled up with fine mortar, and the mouth of the hive should be contracted so as to admit only one bee at a time to pass. It is also proper to furnish the hives with a covering capable of defending them from rain and snow. The usual covering employed for this purpose is a conical head of straw, in which the straws are arranged longitudinally in the way of a thatch, and not too tightly bound together. This throws off the wet extremely well, but it is apt to encourage the attacks of mice and reptiles, who nestle in the straw. It would, perhaps, be better to make the covering of wood, well painted or pitched.

It is no uncommon error to suppose that bees cannot be kept too warm in winter, and many persons cover them up very closely. This, by preventing the natural torpidity of the bees, tends to waste their provisions; and it is now well ascertained, that bees survive the winter in the woods of Siberia, and even when placed in an ice-house.

Feeding of bees.—It is sometimes necessary, when the honey season has been bad, or when too much of the combs has been abstracted from the hive, to feed the bees during a considerable part of winter. They may be fed upon syrup, formed by dissolving a pound of honey, or three-fourths of a pound of sugar, in a quart bottle of good ale, boiling it to a proper consistence. The best method of introducing this into the hives, is by means of joints of what is called sheeps-parsley, or kekses, formed into troughs by cutting away a part of one side between the joints. One of these filled with syrup will generally suffice the bees of a hive for one day. These troughs should be introduced full in the evening, and removed next morning.

The feeding of bees should be begun sometimes before an absolute scarcity takes place in those hives which are known to be too weak to stand the winter; and it is often necessary to have recourse to this expedient in the early part of spring, when the weather is cold and moist.

Preventing depredations.—The preventing of the depredations committed by the various enemies of bees, and counteracting their attacks, require different precautions for almost each species of enemy. We shall here adopt Mr Huish's arrangement, in considering man as their principal enemy, and notice the method he proposes for preserving hives from being stolen. This consists in perforating the post on which the table is placed with a hole sufficiently large to admit a pretty stout chain that passes from an iron hoop passed round the body of the hive, and joined to an iron arch that goes over the top, and securing the chain below by a good padlock. The attacks of field-mice are best prevented by setting traps at some distance from the hive to catch and kill these animals. Huish's trap is simple and ingenious. A thread is passed through a pea soaked in water, and fastened at each extremity to a stick fixed firmly in the ground, and a brick is made to rest in an inclining position on that part of the thread that holds the pea. The mouse coming to devour the pea, bites the thread in two, and is crushed by the falling brick. Perhaps the only method of preventing the attack of birds, is to watch them, and shoot a few, as examples to the rest; or feathers attached to a cord, and fastened to posts, may be placed near the hives, as practised by gardeners, to frighten away the birds from their crops of seed. Lizards and toads should be destroyed wherever seen, and may be prevented from entering the hive by contracting its mouth. It is not easy to prevent the depredations of wasps and ants; and, perhaps, the only certain way is to search for and destroy their nests. The practice of hanging bottles of sweetened water near the hives is absurd, as it attracts insects, and, when near the hive, they will rather enter it, as they prefer honey to sugar. To prevent spiders from constructing their webs within the hive, it is necessary to examine the hive pretty frequently before the depth of winter, and clear away any cobwebs that may have made their appearance. No certain remedy, as far as we know, has been proposed for preventing the ravages of moths that have once entered a hive. These insects always attack the weakest hives; and all that can be done is to transfer the bees into another hive provided with healthy combs.

By way of concluding this part of our subject, we shall give an abstract of what Mr Huish calls the "*Apiarian's Monthly Manual,*" noticing, in a general way, the circumstances to be attended to under each month, beginning with

October.—Examine and weigh the hives; and after cleaning the stools, fasten them down for the winter. See that the coverings are clean and weatherproof; and for the last time remove what combs can be spared.

November.—Inspect the hives, and clean the stools, contract the entrance, and see that the coverings are clean, and the hives so secured as not to be blown off by the wind.

December.—In very cold or snowy weather close the mouths of the hives as much as possible, and clear away any snow that falls upon the table.

January.—Towards the latter end, give the bees more air.

February.—Enlarge the entrance of the hive, and in mild weather inspect the hive and clean the stools. This is a good time for purchasing hives.

March.—Remove all encumbrances from the mouth of the hive, and make every part thoroughly clean. Supply the bees with fresh water. Make an addition to such hives as are strong and heavy, and extract such combs as are old and discoloured. Feed weak hives.

April.—Destroy moths and butterflies. Watch for the signs of swarming; and towards the latter end make artificial swarms, where desireable. Destroy wasps, especially the queens.

May.—Frequently inspect the hives, and clean away every thing offensive. Make preparations for hiving swarms, and keep a good look-out in fine weather.

June.—Feed new swarms in rainy weather, and enlarge such hives as are numerous and active.

July.—Remove part of the produce of the bees. Destroy wasps nests, and inspect the hives for vermin.

August.—Examine and weigh the hives, and take combs from such as exceed 30lbs.

September.—Transport hives to more abundant pastures. Assist in killing drones. Furnish new coverings where necessary. Inspect the hives, clean the stools, and destroy vermin.

It will be readily conceived that these directions do not equally apply to every part of Britain; and in general we may remark, that as the climate in the northern parts is about a month later than that in the southern, allowance must be made accordingly.

BEE-EATER, a bird. See *Merops*, under ORNITHOLOGY.

BEE-FLOWER, a species of Ophrys, a genus of plants belonging to the Gynandria class.

BEE-GLUE, the propolis of the ancients, a glutinous matter with which bees cement the comb to the hive, and close up their cells. See BEE.

BEER, a fermented liquor obtained from an infusion of malted grain. See BREWING.

BEERING, or BEHRING'S ISLAND, an island in the North Pacific ocean, in the 55th degree of N. latitude, and forming one of the group called Aleutian islands, derives its name from the discoverer, commodore Behring, who was driven upon it in 1777; and, after experiencing the severest hardships, fell a victim, along with many of his crew, to the rigours of the climate. See ALEUTIAN ISLANDS.

BEERING, or BEHRING'S STRAITS, the channel which separates the continents of Asia and America, in the 65th degree of north latitude, and is about 40 miles in breadth; was discovered by commodore Behring in 1728, whose name it bears. In 1778 this strait was explored by captain Cook, and in the succeeding year by captain Clerk; several geographical positions were settled by these celebrated navigators; the depth of the water in the channel did not exceed 20 or 30 fathoms; and a remarkable similarity in the low naked shores with elevated land in the interior of the country, was observed on both sides of the straits. Three small islands occupy the middle of the channel. In 1790 Behring's straits were visited by some ships sent out by the Russians; but in all attempts to reach higher latitudes, immense fields of ice have always presented an insurmountable barrier. Cook's *Voyages*. Coxe's *Russian Discoveries*.

BEGUINS, a religious order of nuns, which was first established at Liege about the beginning of the 13th century, and spread over Flanders, the Low Countries, and Germany. The most flourishing societies of this order were in Antwerp, Malines, and Amsterdam.

BEHEMOTH, the scriptural name of a large and strong animal, supposed by naturalists to be the riverhorse or hippopotamus, which see under MAMMALIA.

BEHEM, or BEHEIM, MARTIN, a navigator of the 15th century, for whom the honour of the discovery of America has been claimed. He was a native of Nuremberg in Germany, and was early attached to the study of astronomy and navigation, in which it is probable he was encouraged by his instructor, the celebrated Regiomontanus, or John Muller. Endowed with an enterprising spirit, he made an offer of his services to Isabella of Portugal to undertake a voyage of discovery; being provided with a vessel, he sailed westward in the Atlantic ocean; and in 1460 discovered Fayal and the other islands of the Azores. He obtained a grant of Fayal, established a colony, and resided on it for about twenty years. In 1484 he was furnished with ships by John II. king of Portugal for another expedition, in the course of which he discovered Brazil and the straits of Magellan. As a reward for these remarkable discoveries, he was loaded with the most distinguished honours by the king of Portugal.

In 1492, the remarkable year of the discovery of America by Columbus, Behem visited his native city; and during his residence there, it is said he constructed a terrestrial globe, which is still preserved at Nuremberg. On this globe are traced the course of his own voyage, and the western regions, supposed to be the coast of Brazil, which he discovered.

The claims advanced for Behem are of a doubtful character. It seems to be quite unaccountable how so remarkable a discovery should be kept in profound silence for the period of eight years; and even long after the fame of the brilliant enterprise of Columbus, no notice was taken of any previous claim. The construction of the globe in the very year in which Columbus made his discovery, if the evidence of that fact be indisputable, presents a singular coincidence, and excites some suspicion that the dates may not be precisely stated. Behem died at Lisbon in 1506. Those who wish to see the claims of this navigator more fully considered, may consult a Memoir in the 2d volume of the American Philosophical Transactions

BEIRA, a province of Portugal, which is bounded by the river Douro on the north, by the Tagus and part of Estremadura on the south, by the ocean and part of Estremadura on the west, and by the Spanish territory on the east; is about 30 leagues square, and presents a diversified surface of steep mountains and fertile valleys.

The rocks of which the mountains are composed belong chiefly to the primitive class. Granite, micaceous, and argillaceous schistus predominate in the lofty ridges, and are succeeded at a lower elevation by grey limestone alternating with coarse-grained sandstone; some indications of coal have been observed on the coast, but not of sufficient extent to encourage active operations. The Mondego, which is the principal river, traverses the greater part of the province, and in its course towards the ocean passes through many rich and beautiful valleys. The mountains are clothed with forest-trees, and the plantations of olive-trees are extensive.

The population of Beira is stated at 560,000. The chief towns are Coimbra, Lamego, Guarda, Aveiro, Almeida, &c. Some parts of the province are under good culture; and wheat, barley, and rye are raised. Indian corn is cultivated in considerable quantities, and crops of rice are obtained from the marshes along the banks of the Mondego. The fruits of Beira are abundant and excellent; and the oranges, which are of a superior quality, are enumerated among the exports, to which also may be added the produce of the vine. The more elevated districts afford good pasture to sheep and cattle.

BEJAPOOR, a province of the Deccan in India, is about 350 miles long, and about 200 miles broad; is traversed by a mountainous ridge, which is a branch of the western Ghauts, for more than 60 miles from the sea, is watered by numerous rivers, and includes a population of 7,000,000, of which the followers of Brahma form the larger proportion, and the rest profess the Mahometan creed. Bejapoor and Poonah are the principal towns; but there are others of considerable magnitude, in which extensive manufactures of silk and cotton are successfully conducted, and their commercial intercourse with the northern regions of India is prosperous and lucrative. This province, once an independent kingdom, has been torn with dissensions among rival or rebellious chiefs; but, by the prudent interference of the British government, in 1804, some degree of tranquillity was restored, and probably the same powerful influence may be requisite in future to keep them in subordination.

BEL, or BELUS, the supreme god of the ancient Chaldeans, is supposed to be the Nimrod of Scripture, and the Phœnician Baal, and the founder of the Babylonian empire. The statue of this god was set up and dedicated by Nebuchadnezzar in the plain of Dura, after his return from the Jewish war. Daniel, chap. iii.

BELEM, a town of the province of Estremadura in Portugal, stands on the north bank of the Tagus; is the burial place of the Portuguese royal family, and is remarkable for a monastery of singular and fanciful architecture. One of the churches is a fine Gothic structure. Belem could once boast of a royal palace. It is still the residence of wealthy tradesmen, and is adorned with a botanic garden and the royal gardens, which still remain. A tower and several batteries, with a small fort for the defence of the harbour of Lisbon, have been erected at no great distance. Belem is three miles west from Lisbon.

BELEMNITES, known by the name of *thunder-stones*, or *thunder-bolts*, are organised substances in a petrified state, which are found detached in beds of gravel or clay, or are embedded in limestone, and are generally supposed to be animal remains. They are of a conical form, internally of a radiated structure, and are from one inch to five or six inches in length. According to the opinion of Klein, the belemnites are the spines of a large species of sea hedge-hog.

BELFAST, the most populous town in the north of Ireland, stands on the north side of the river Lagan, in the county of Antrim, and at its influx into Belfast lough, or Carrickfergus bay, and is about 80 miles north from Dublin. Although Belfast can lay claim to some antiquity, yet it was only a small place in the beginning of the 18th century; but by the enterprising spirit and commercial activity of its inhabitants, it has become one of the most flourishing towns in the kingdom. In the modern part of Belfast, the streets are spacious and regular; the houses, which are chiefly of brick, are well built; and the public buildings, as the exchange, the linen hall, some of the churches, and the college, are plain, but elegant and commodious structures. A bridge of twenty-one arches forms the communication between Belfast and the suburbs in the county of Down. It was built about the time of the revolution, at the expence of L.12,000, contributed by the two counties. Commodious docks, and yards for building and repairing ships, have been constructed at Belfast. Vessels of moderate size unload at the quays, but ships of large burden discharge their cargoes three miles below the town. By late improvements, the depth of water has been considerably increased.

The population, stated at 13,000 in 1782, was estimated at 30,000 in 1810, but it is supposed that this number is underrated. The chief manufactures are linen and cotton, earthen ware, glass, and sugar; and along with ship-building, some cast iron founderies and chemical works are prosperously conducted. Beside the coasting trade, and the exchange of commodities with England and Scotland, the commercial intercourse of Belfast with America and the West Indies is very considerable. In 1809, the exports of linen, butter, salted provisions, and oatmeal, amounted nearly to L.1,911,000 Sterling.

The charitable institutions of Belfast are numerous and liberally supported; the various literary societies, and public libraries which have been established, afford ample evidence of the intelligence and taste of the inhabitants; private academies have been long successfully conducted; and the Academical Institution, the building of which commenced in 1810, and was completed at an expence of more than L.16,000, raised by subscription, will form a remarkable era in the history of Belfast. This institution embraces a wider field for the education of youth, and is intended to include all those branches of literature and science which are usually prosecuted by the general scholar. Teachers have been appointed in several departments; their labours have begun, and promise to be of incalculable benefit to the northern division of the kingdom.

BELGÆ, a people of ancient Gaul, who occupied that district of country which lies between the Rhine and Loire, and are particularly described by Cæsar in his Commentaries.

BELGIUM was a part of ancient Gaul. The name was revived by the French in their revolutionary progress in 1795, and applied to the Netherlands, which, with the bishopric of Liege, was annexed to France, and divided into nine departments. The whole is now included under the new kingdom of the Netherlands.

BELGRADE, the capital of the province of Servia in European Turkey, stands on the declivity of a hill at the confluence of the Save and the Danube; was formerly a strongly fortified and populous place, and is still distinguished for its commercial transactions. The caravanseray or public inn, the college, the exchange, and the bazars, or market-places, are the principal public buildings. The streets are covered with wood, as a shelter to those who are engaged in mercantile affairs. Not far distant from Belgrade, some magnificent aquæducts were constructed by the eastern emperors, and were repaired and extended by their successors.

The population of Belgrade is estimated at 25,000; the situation is peculiarly favourable for commerce, having the commodious communication of the Danube with Germany and the rest of Europe on the one hand, and with the Black sea and the regions of the East on the other; and hence it is the constant resort of merchants from all these countries. The distance from Constantinople is stated at 440 miles north-west.

Regarded as the key to Hungary, Belgrade has

Belisarius. Bell.

been often the scene of severe struggles for its possession between the Turks and Austrians. It was taken by Solyman the Magnificent in 1521; recovered by the Austrians in 1688; and again, in 1690, after a cruel massacre, fell into the hands of the Turks, to whom nine years afterwards it was confirmed by treaty. But the most sanguinary contest which Belgrade had yet witnessed, was exhibited in 1717, when prince Eugene with 90,000 men laid siege to the place, on the 16th of August of that year attacked a Turkish army of 200,000 men which had come to its relief, and, after a terrible slaughter, obtained a complete victory and possession of the town. After another fruitless attempt, and the demolition of the fortifications, the Turks became its masters by treaty in 1739. It yielded again to the Austrians in 1789, and was restored by the peace of 1791, since which time it has continued in possession of the Turks.

BELISARIUS, a celebrated general under the emperor Justinian, is supposed to have been a native of Thrace, and rose from the humble rank of one of the private guard to the distinguished station of commander of the imperial armies. Having performed the most splendid exploits, and in the progress of his victorious career in the east and the west, in Italy and Africa, having added innumerable laurels to the Roman arms, and acquired the highest military reputation, he was falsely accused of a conspiracy against the emperor. The real conspirators were detected and seized with arms concealed under their garments. One of them fell by his own hand, and another, torn from the sanctuary to which he had fled, being tempted by the hopes of safety, charged two officers of the household of Belisarius, who being subjected to torture, declared that their patron was implicated in the crime. "Posterity will not hastily believe that a hero who, in the vigour of life, had disdained the fairest offers of ambition and revenge, should stoop to the murder of his prince, whom he could not long expect to survive. His followers were impatient to fly; but flight must have been supported by rebellion, and he had lived long enough for nature and for glory. Belisarius appeared before the council with less fear than indignation. After forty years service, the emperor had prejudged his guilt, and injustice was sanctified by the presence and authority of the patriarch. The life of Belisarius was graciously spared; but his fortunes were sequestrated; and from December to July he was guarded as a prisoner in his own palace. At length his innocence was acknowledged; his freedom and honours were restored; and death, which might be hastened by resentment and grief, removed him from the world about eight months after his deliverance. That he was deprived of his eyes, and reduced by envy to beg his bread, "Give a penny to Belisarius the general," is a fiction of later times, which has obtained credit, or rather favour, as a strange example of the vicissitudes of fortune." The source of this idle fable is traced to a miscellaneous work of the 12th century, the Chiliads of John Tzetzes, a monk, who relates the blindness and beggary of Belisarius in ten vulgar or political verses. This moral or romantic tale was imported into Italy with the language and manuscripts of Greece, and repeated before the end of the 15th century by several authors.

Belisarius died in the year 565, leaving behind him the character of a consummate general,—humane and liberal to his soldiers, whom he kept at the same time under the most rigid discipline,—not less humane and tender to those whom victory had put into his power,—and remarkable for his humility in prosperity, for his temperate habits, and his forbearance and self-denial in the midst of all his good fortune. Gibbon's *Roman History.*

BELL, a machine which produces sound, for the purpose of communicating different kinds of signals, and which is sometimes employed as a musical instrument. The form, size, and uses of bells are extremely different. An alloy of copper and tin is usually employed in casting bells; and hence it is known by the name of *bell-metal.* In most bells that have been examined the proportions are nearly the same. The component parts of bell-metal have been found to be 75 of copper and 25 of tin, or three of copper and one of tin. In fragments of bells that have been subjected to analysis, a small proportion of other metals has been detected, such as zinc, antimony, bismuth, and silver. But these metals are not supposed to be essential to the alloy, although it is probable the sonorous property may be somewhat modified by the addition.

The form of bells varies in different countries, approaching in some cases more nearly to that of the cylinder, and in others to that of the cone. But, according to Reaumur, the best shape of a bell would be that of the segment of a sphere, for even lead, which is the least elastic of the metals, when cast into this form, is very sonorous. In large bells a certain proportion is sometimes observed between the thickness and the size; the thickness of the edge is one-fifteenth of the diameter, and the height is twelve times the thickness.

Uses of bells.—Whatever may have been the origin of bells, their use, which has been very various, may be traced to the remotest antiquity. The sacred vestments of the Jewish high-priest were decorated with golden bells, for the purpose, it is supposed, of announcing his presence, of communicating to the people the moment that he entered the sanctuary. The garments of the ancient kings of Persia were furnished with bells in a similar manner, and, it has been conjectured, for the purpose of giving warning of their approach, that those who should be admitted to their presence might be prepared to express the proper degree of respect and veneration. Bells were in use among the Greeks to call the people together to religious exercises, as a signal for the sale of provisions, and as a warning to the sentinels on duty in a camp. The Romans announced to the people the preparation of the baths by the ringing of bells; and as bells were suspended from the gates of their temples, it appears that they were employed in the same way, or in some part of the religious service.

The practice of hanging bells from the necks of animals, which is alluded to by ancient writers, has been continued in modern times, and is intended to prevent the depredations of rapacious wild animals among herds and flocks, or, according to some, to answer some superstitious end. To a similar use are assigned the bells worn by the leading horses or mules employed in carrying loads on their backs, as was formerly the case in Britain before the improvement of the roads and the introduction of carriages, and is the case at the present day in many parts of the continent.

Bells were used in the churches of Italy, it is supposed, about the commencement of the 5th century, and before the end of the 7th they were introduced into England. In the beginning of the 11th century bells seem to have been part of the regular establishment of religious houses; for a portion of the revenue was appropriated to their purchase and repair. The Greek Christians, it is said, were unacquainted with bells till the ninth century, but they were afterwards prohibited by the Turks from using them. Such a prohibition might be expected from the followers of Mahomet, who, perhaps from policy, has excluded bells, to mark more strongly, even in trivial matters, the distinction between his system and Christianity.

Bells appropriated to churches and religious houses were formally consecrated and named about the tenth century. The episcopal benediction was pronounced, and the honour of the name was usually assigned to some saint. In the dark ages of superstition, the ringing of bells was practised for various purposes,—to warn all Christians to pray for the departing soul,—to drive away the evil spirits that hover in the air,—and to allay the fury of the storm and the tempest. The passing-bell of the present day no doubt refers to the same supposed influence, and the use of bells in modern times is well known. Beside the ordinary purpose of warning to the public exercises of religion, the ringing of bells is a signal of rejoicing on the occurrence of prosperous events, or anniversary festivals; and tolling is an expression of mourning during a funeral procession.

Ringing bells in change, or in regular peals, is said to be a practice peculiar to England, and hence this country has been designated by foreigners the *ringing island*. The bells employed in ringing peals have different tones, and by the skill and ingenuity of the performer a variety of musical sounds, and some degree of harmony, are produced. For the practice of this favourite art societies have been established; it is conducted according to certain principles, and peals which bear the names of the authors have been composed, and are much admired. But the perfection of the art in England seems to consist in the number and variety of the changes, and challenges between rival performers are not uncommon.

In some of the towns of Britain, as well as on the continent, regular tunes are played with bells, which are hence denominated music bells. The performance is conducted by means of keys like those of the piano-forte. It is supposed that music bells were introduced previously to the 14th century. The great tower of the cathedral in Antwerp is furnished with a splendid set of music bells. The number of bells is thirty-three, and the largest is eight feet in height, and seven feet in diameter. The fine tone of this bell is greatly admired.

Large bells.—In the history of bells, in different places of the world, their magnitude is not the least remarkable circumstance. Of three bells presented by Edward III. to St Stephen's chapel in Westminster, the largest was 33,000 pounds weight, which appeared from an inscription cast in the metal. The bell in the steeple in the great church at Rouen in Normandy, in France, according to its inscription was equal to 40,000 pounds weight. China is celebrated for large bells; the great weight of the bells in a tower at Nankin brought the building to the ground. The dimensions of one of the bells, which is of a cylindrical form, are 12 feet in height, and $7\frac{1}{2}$ feet in diameter. But of seven bells in Pekin each is said to weigh 120,000 pounds.

The bells now mentioned are far exceeded by the huge bell at Erfurth in Germany; it was cast in 1497; the clapper was 12 feet long, and weighed 1100 pounds; the whole weight is equal to 252,000 pounds, and the sound, in the direction of the wind, was heard at the distance of nine leagues. The bell in the tower of St Ivan, at Moscow, which is 114,000 pounds weight is $13\frac{1}{4}$ feet in diameter, and $16\frac{3}{4}$ inches thick. These are still exceeded by a bell at Moscow, which was made in 1653, but it was never removed from the pit in which it was cast. The scaffolding over it accidently took fire, and the water employed in the extinction of the flames, coming in contact with the heated metal, produced a fracture on one side, which rendered it useless. The rim is buried in the the earth, but the diameter, two feet above the ground, is 22 feet 5 inches, the perpendicular height is more than 21 feet, the thickness 23 inches, and the whole weight equal to 443,772 pounds. This bell, it is said, contains a large proportion of silver in its composition, for the nobles and people contributed a great deal of money and plate, which they threw in as votive gifts while the metal was in fusion. This bell, it is added, is held in superstitious veneration by the Russians, and is visited by peasants on festival days; but it seems more probable that it is regarded as an object of curiosity on account of its extraordinary magnitude.

BELL-ROCK LIGHT-HOUSE, on the eastern coast of Scotland, is 11 miles south-west from Redhead in Forfarshire, 12 miles from Arbroath, 17 miles north-east from the May light-house, and 30 miles north by east from St Abb's head. Its geographical position is in 56° 29′ of north latitude, and 2° 22′ of west longitude. The rock is composed of red sandstone, similar to the strata of the contiguous promontory of Forfarshire and of the shores of Berwickshire. During low water of neap tides, a very small part of the rock is seen at low-water; but during the lowest ebbs in spring-tides, a space equal to 427 feet in length, and 230 in breadth, appears about 4 feet above the surface of the water; and from the floating sea-weed, the ridge can be traced 1000 feet farther in a south-westerly direction, when the tides are very low. Such a mass of rock concealed from view during great part of every tide, was an object of great danger to the numerous vessels which navigate that coast. The means of obviating these dangers were long under the consideration of those to whom this department of maritime affairs is en-

Bell-rock. Bellarmin.

trusted; and indeed, at a very early period, if the traditionary story be true, an attempt was made by the abbots of Arbroath to erect a bell, which was rung by machinery, acted upon by the motion of the tides, to warn the mariner of his danger; and hence it is said the name of Bell-rock is derived.

By a legislative enactment which was passed in the year 1806, the commissioners of northern light-houses were empowered to levy a duty from all vessels frequenting the ports between Peterhead and Berwick; and after various plans for a light-house were suggested, a structure similar to the Eddystone was adopted. Considering the near resemblance of the two situations, it is somewhat remarkable that any other plan for a light-house on the Bell-rock should have been for a moment contemplated than that of the Eddystone, which has so long resisted the tremendous fury of the billows rolling into the channel from the Atlantic ocean, and is one of the noblest monuments of the genius and perseverance of Smeaton, who planned and conducted the work.

Construction of the light-house.—Early in 1807, the preparation of the materials for building the light-house commenced. The stones were obtained from the granite quarries in Aberdeenshire, or from sandstone quarries in the vicinity of Dundee and Edinburgh, and they were either prepared on the spot from which they were dug, or in the yard established at Arbroath for the use of the undertaking. The cement was a mixture of puzzolana earth, lime, and sand, in equal proportions. When the operations commenced at the rock in August, the first object was the erection of a wooden beacon-house, for the safety of the workmen, in case any accident should happen to the boats which were in attendance to carry them to the vessel with the floating light, which was moored at the distance of a mile and a half. This temporary edifice, supported by large beams of fir timber, was raised 50 feet above the surface of the rock. The upper part of it was afterwards fitted up as a smith's forge, a kitchen, and lodgings for the engineers and workmen. The beams were set up by the end of October, and the different apartments were prepared in the early part of the ensuing summer. The foundation stone was laid on the 10th of July 1808, and in the close of the season four courses, which raised the height of the building five feet six inches above the foundation, were finished.

When the operations were resumed in the spring of the year 1809, it appeared that the works of the preceding season had not sustained the least injury from the severity of the winter storms; and during this summer the building was raised to the height of 30 feet. This completed the solid part of the edifice. All the materials for finishing it being collected and prepared, the operations commenced as early as the weather permitted in 1810; and by the activity and experience of both seamen and artificers, the whole was completed in the month of December, and the new light was exhibited on the first of February 1811.

Description of the building.—The Bell-rock light-house is a solid mass of building from the foundation to the height of 30 feet. The two lower courses of the masonry are imbedded in the rock. The outside casing is of Aberdeen granite; the internal parts of the solid mass are sandstone. The stones employed were from two tons to half a ton each in weight, and the stones of each course are not only connected together, but the different courses are firmly united to each other. The foundation of the building is forty-two feet in diameter, and it diminishes gradually to the top, where the diameter is only thirteen feet. The lower part of the walls is seven feet thick, and they also diminish to one foot in thickness at the parapet wall of the light room. The masonry is 100 feet in height, and the height of the whole edifice, including the light room, is 115 feet.

Beside the light-room, the Bell-rock light house contains five apartments for the accommodation of the light keepers, and for the reception of provisions and necessary stores. The light-room is of an octagonal form, 12 feet in diameter and 15 feet in height, formed of cast iron sashes, filled with plate glass nearly $2\frac{1}{2}$ feet square, and 1-4th of an inch thick, and it is covered with a copper dome. The light is obtained from oil burnt in Argand's lamps, placed in the focus of silver-plated reflectors. By means of machinery, the whole lights move round on a perpendicular axis every six minutes; and during each revolution, a bright white light, a red light produced by the interposition of red glass, and alternate intervals of darkness, distinguish the Bell-rock light from every other. In hazy weather two large bells are tolled day and night by the same machinery.

Four light keepers are appointed to the Bell-rock, at salaries of 60, 55, and 50 guineas yearly, beside a stated allowance of provisions, and other perquisites, when on duty, and apartments for their families at Arbroath. Three of them always attend at the light-house for six weeks, while one is permitted to be on shore for a fortnight, during which time he takes charge of the signal tower at Arbroath, from which a correspondence is kept up with the light-house by signals.

The whole expence of this remarkable edifice is stated at L.60,000; and the skill and perseverance of the engineer Mr Stevenson, in the speedy and successful completion of so arduous a work, have been only equalled by his great predecessor Mr Smeaton, in a similar undertaking.

BELLARMIN, Robert, an Italian Jesuit, and one of the ablest controversial writers of his age, was a native of Tuscany, and was born in 1542; in his 18th year he entered the society of Jesuits, and when he was admitted to the priesthood, from being a near relation of the reigning pope, saw the path of ecclesiastical preferment open before him. Appointed professor of divinity at Louvain, he delivered lectures for seven years, which were characterised by ingenuity and acuteness; and repeating them at Rome, when he returned to his own country, he acquired a high degree of reputation. Being engaged in various public missions by three successive popes, he was at last raised to the dignity of cardinal, which it is said he reluctantly accepted; was afterwards elected archbishop of Capua, and was excluded from the chair of St Peter only because he belonged to the order of Jesuits. His powerful talents rendered his services of great importance to the church; and during the latter years of his life he resided constantly at the court of the Vatican. His growing infirmities required him to withdraw from public affairs in 1621, and he died in the same year, at the advanced age of 79. Bellarmin was a voluminous and elaborate writer. His principal work, *A Body of Controversy*, in four volumes folio, which has been often quoted by his opponents, is distinguished by fairness and candour, clear arrangement, ingenious reasoning, and plain, nervous language.—*Gen. Biography.*

BELLEISLE, an island in the bay of Biscay, included in the department of Morbihan in France, and about fifteen miles from the coast; is about twelve leagues in circumference; the shores are rugged and precipitous, and the surface is partly rocky and barren, and partly covered with good soil, which produces some grain. The inhabitants, the number of which is variously stated from three to 5000, are chiefly employed in the pilchard fishery, which is abundant and lucrative, and is the principal source of their commercial intercourse with other parts of France and some parts of Spain. Besides Palais, the chief town, numerous villages are scattered over the island. An unsuccessful attempt on this island was made by the British in 1761, and in the repulse 500 men were slain. In a second attack possession was obtained; but it was restored by treaty in 1763.

BELLENDEN, John, a Scottish poet, who flourished in the 16th century; but the records of his life are so scanty that little is known of the time of his birth, or of the place of his education. He was archdeacon of Moray, and it is supposed that he died at Rome in 1550. He was in great favour with James V. of Scotland, at whose suggestion he undertook the *History and Croniklis of Scotland*, which is a free translation of the first seventeen books of Hector Boyce's history. Two poems, the *Proheme of the Cosmographe*, the chief incidents of which are derived from the ancient allegory of the choice of Hercules, and the *Proheme of the History*, appear in the same publication, which is concluded with a prose epistle addressed to the king. The noble enthusiasm which pervades the poetry of Bellenden has placed him in the first ranks of the poets of his country; and, with a fine fancy and cultivated taste, his learning was extensive and profound.

BELLEROPHON, a celebrated character in ancient mythology, was the son of a king of Epirus; and having accidentally killed his brother, fled to the king of Argos for protection. His queen, disappointed in her attempt to seduce the stranger, brought a false charge against him, but the king, doubtful of its truth, or unwilling to inflict punishment, sent him to his father-in-law, the king of Lysia, by whom he was employed in several hazardous enterprises. Bellerophon not only escaped the danger to which he was exposed, but returned victorious. One of his exploits was the destruction of the Chimæra, in which he was greatly aided by the horse Pegasus, furnished by Minerva or Neptune.

His royal host, convinced of his innocence and integrity, and delighted with his heroism, gave him his daughter in marriage. But prosperity made him vain and ambitious. With his divine animal he attempted to scale the celestial regions. Jupiter, to check his presumption, struck him blind, and threw him down to the earth, on which he wandered a miserable spectacle of divine wrath till his death; but, by the permission of Jupiter, Pegasus ascended to heaven, and was placed among the constellations.

BELLES LETTRES, a French expression, literally signifying *fine letters*, is a term of common occurrence, and may be considered as naturalised in the English language, but with no very definite meaning, is nearly equivalent to the phrase *polite literature*, of equally general import, and is usually understood to refer to knowledge of grammar, criticism, and what may be considered the ornamental branches of learning.

BELLIS, the Daisy, a genus of plants belonging to the Syngenesia class, of which the well-known common daisy, *bellis perennis*, is a species.

BELOOCHISTAN, or Baloochistan, an extensive region of Asia, on the north-west coast of the Indian peninsula, has the Indian ocean for its boundary on the south, Affghanistan on the north, the Persian territories on the west, and Sinde on the east; extends from the 25th to the 30th degree of N. Lat. and from the 58th to the 68th degree of E. Long. and includes an area of more than 150,000 square miles. This district is traversed in various directions by mountainous ridges, some of which rise to a great elevation. The rivers are to be regarded as mountain torrents, which flow down with irresistible rapidity during the rainy season, and, when the drought prevails leave a dry channel.

The mountains afford metallic ores, such as those of iron and copper, which are smelted and manufactured, and even some of the more precious metals. The climate and soil are various. Some districts are fertile, and produce corn and fruits in abundance. In the desert and less frequented tracts, wild animals of the fiercer kinds are not uncommon. Kelat, which is walled and fortified, is the principal town and capital of the country, and, including the suburbs, contains about 4000 houses constructed of wood or half-burnt bricks. The houses are lofty, the streets are narrow, and the projecting upper stories cast a gloomy shade on the vacant space below.

Many of the native tribes of this district lead a pastoral life, live in tents, and, like other wandering tribes, are not scrupulous of engaging in plundering warfare. They are all believers in the Koran. Each tribe is said to elect its own chief, but this choice, it is probable, most frequently falls on the strong and powerful. The khan, or prince to whose authority all the chiefs submit when he possesses the means of enforcing it, resides at Kelat. But, like other rude states, the government of Beloochistan has been subject to many vicissitudes.

BELLONA, the goddess of war of ancient mythology, is variously described as the sister, wife, or daughter of Mars, for whom she prepared the chariot, and is commonly represented in a state of fury and distraction, her garments stained with blood, and her snaky hair clotted with gore; and with a trumpet, a lighted brand, or a bloody whip in her hand, she drives the chariot of the god of war. Temples were erected to the worship of Bellona at Rome and in the provinces, among which it is recorded that one was dedicated to the same goddess in York in England, in the time of Severus.

BELLONIA, a genus of plants belonging to the

Pentandria class, of which the only species is a native of the warmer parts of America, and is named to commemorate Peter Belon, a French naturalist of the 16th century.

BELLOWS, a machine for blowing air with violence, for the purpose of increasing the heat of common fires, furnaces, and forges, or for producing sound in organs and other musical instruments. When bellows are employed on a large scale, and when the pressure of water is brought into action to produce a uniform and uninterrupted current of air, the apparatus thus constructed is called a *blowing machine*, for an account of which see FURNACE.

BELLUNESE, a mountainous district of Italy, included in the Venetian territory, part of which is clothed with extensive forests, from which large quantities of timber are floated down the river to Venice; part affords excellent pasture to numerous herds of cattle, and part yields abundant crops of corn and fruits. Metallic ores abound in some of the mountains. The population exceeds 47,000. A dreadful disaster happened in this district in the year 1774. A mountain, thrown down by an earthquake, filled up the bed of a river, buried under its ruins seven villages, with all their inhabitants, and formed a permanent lake two miles in length, and half a mile in breadth.

BELLUNO, the capital of the Bellunese in Italy, stands on the banks of the river Piava, contains more than 7000 inhabitants, and, by means of the navigable river, has a considerable trade. Belluno is adorned with many fine buildings, some splendid marble monuments, and numerous churches, monasteries, and hospitals.

BELON, PETER, a French naturalist, who flourished about the middle of the 16th century, and published various works on birds, fishes, serpents, &c. which are occasionally quoted by later naturalists, and an account of his travels in Greece, Egypt, Arabia, and other eastern countries. He lost his life by the hand of an assassin, near Paris, in 1564.

BEMBA, or BEMBEA, a province of Angola, which stretches partly along the coast, is said to be extremely populous, and abounds with cattle. The river which traverses this province swarms with crocodiles and river horses. Numerous serpents infest the less frequented parts of the country; but serpents devouring fish must either be admitted as a fact unknown to naturalists, or must be regarded as an exaggerated tale imposed on the credulity of some traveller; and perhaps the story of the inhabitants clothing themselves with the skins of cattle may be traced to the same source. The natives of warm climates neither require nor make use of such a dress.

BEMINSTER, a town of Dorsetshire, in England, is finely situated in the midst of gardens and orchards, in a fertile valley, on the banks of the river Bist. The population exceeds 2000, and manufactures of woollen stuffs and sail-cloth, of iron and copper wares, are established. Beminster is 12 miles from Dorchester, and 138 miles west from London.

BENARES, a province of Hindostan, in the East Indies, which is bounded on the east by Bahar, and on the west by Allahabad, and extends about 70 miles in length, and 25 miles in breadth, is very populous, and possesses a rich and fertile soil. This country was ceded to the British in 1775, and, it is said, affords a clear annual revenue of L.400,000 sterling.

BENARES, the capital of the district of the same name in the East Indies, is celebrated as the ancient seat of Brahminical learning, stands on the northern bank of the Ganges, about 460 miles north-west from Calcutta. The streets are in general narrow, and approach so near in some places that they are united by galleries. The houses are built with stone, and some of them are raised six stories high, each of which is inhabited by a different family. The windows are extremely small, for the purpose, it is supposed, of precluding opposite neighbours from seeing into the apartments, or for preserving coolness during the prevalence of hot winds. A large proportion of the houses of Benares is constructed of mud; but the more opulent inhabitants possess detached houses, which have open courts, and are inclosed by walls. The banks of the river are embellished with numerous Hindoo temples, and many of the public and private edifices are magnificent structures. In the centre of the city a large mosque, with its towering minarets, was raised by the emperor Aurengzebe, on the same spot which was occupied by a splendid Hindoo temple, and is regarded by the natives as an insult and profanation of their worship.

In the vicissitudes of its fortunes, Benares has greatly declined; but many monuments of its ancient splendour yet remain. The celebrated Observatory, which is furnished with numerous astronomical instruments, formed of stone, and constructed with great accuracy, is still preserved, and Benares is yet resorted to by students from all quarters, to be instructed in the literature and science of the east.

The population of Benares has been variously estimated at 150,000, from three to four hundred thousand, and, according to some calculations, the number of inhabitants exceeds half a million. During certain festivals, an immense concourse of pilgrims resorts to Benares from all parts for the purpose of performing their devotions; and the pictures of hunger, wretchedness, and disease which present themselves among the multitudes assembled on these occasions, as they are described by travellers, seem to exceed belief.

BENCOOLEN, a sea-port town on the south-west coast of Sumatra, stands on morassy ground, and is above two miles in circumference. The houses are raised on bamboo pillars, the inhabitants are occupied in fishing, and in the culture of rice and pepper, which is the chief commercial commodity. The surrounding country is mountainous, and clothed with wood; and a spacious and commodious bay stretches for several leagues in front of the town.

BENDER, a fortified town, and capital of Bessarabia in Turkey in Europe, stands on the banks of the Dniester; and before the memorable and disastrous siege in 1770, when it was invested and stormed by the Russians, the population amounted to 30,000, but by famine and war was reduced to less than half the number. The fortress, erected in consequence of the dying command of Bajazet II. to his successor, is remarkable for a spacious ditch, is well furnished with cannon, and fully supplied with ammunition of all kinds. The mosques, some of which are fine edifices, gates of the town, and inns, are numerous; but the streets are narrow, gloomy, and dirty. Manufactures of leather and paper have been established; and part of the inhabitants is occupied in watch-making, and in the construction of implements and utensils of iron. Bender is memorable in history as the place to which the famous Charles XII. of Sweden retired after the battle of Pultowa, when he sought an asylum from the Turks; and the ruins of the house in which he resided, and some remains of the entrenchments which he constructed are yet visible.

BENEDICTINES, an order of monks which was instituted in the year 529 by St Benedict, from whom the name is derived. The corruptions which had crept into the other monastic institutions brought them into disrepute; and the regular system of discipline which prevailed in the rule of St Benedict soon gave it a high degree of celebrity. About the 9th century the Benedictines had taken place of almost every other order in France, Italy, Germany, and England. The decline of the order is dated from the middle of the 10th century; and in the attempts to reform and restrain the irregularities which marked their conduct, they were at last in a great degree superseded by the order of Clugny, which became no less celebrated throughout Europe.

BENEDICTION, a form of prayer or thanksgiving pronounced sometimes on more ordinary and sometimes on more solemn occasions. Among Christians the short prayer before meals, and the expression of thanks after a repast, come under the denomination of benediction. The patriarchs, in the prospect of death, left their blessing with their families; certain forms of benediction were established among the Jews; and similar practices prevail both among Christians and Mahometans. Among the latter, indeed, it is often little different from the friendly forms of salutation in common life. Benediction may be regarded as part of the ceremony of consecration in the Christian church, when a person, or even an inanimate object, is set apart for the service of religion.

BENEVENTO, a city of Naples, which is chiefly remarkable for numerous remains of Roman antiquity. The *porta aurea*, or golden gate, one of the entrances to the city, is a splendid monument of white marble, erected by Trajan, about the beginning of the second century, to commemorate the wars in which he had been engaged with the Dacians; and fragments of tombs, altars, and ornamental pieces of architecture are seen in the walls of every modern house in one part of the town. The population of Benevento is stated at 10,000, and the distance from Naples is 30 miles.

BENGAL, a province of Hindostan, which has the bay of the same name for its boundary on the south, Orissa and Bahar on the west, Assam and Bootan on the north, and on the east a mountainous range which forms a natural limit between it and Arracan and the Birman territory. Bengal extends from the 21st nearly to the 27th degree of north latitude, and from the 86th to the 93d of east longitude; and the greatest length from east to west is about 700 miles, and the greatest breadth from north to south is about 300 miles.

Climate.—The climate of Bengal is subject to great extremes of heat and cold. During the hot season, which commences with March, and continues three months, the thermometer often rises to 100; in the cool season, between November and February, the north winds chiefly prevail, and the sky is serene and unclouded; but from June to October, in the intermission of the heavy rains, thick fogs are common, and the weather is sultry and oppressive.

Aspect and soil.—In the south-west corner of the province, and on the north of the Ganges, the country rises to a considerable elevation; but Bengal, in general, is to be regarded as a flat region, traversed by numerous rivers. The majestic streams of the Ganges and Burrampooter flow through the richest districts of Bengal, and in their annual inundations communicate a high degree of fertility to the contiguous lands. The Ganges discharges its waters into the ocean by several branches, which intersect the lower district, or Delta, in various directions. The whole region which extends from the river Hooghly to Chittagong, is distinguished by the Indian name of *Sunderbunds*, or woods, and is altogether an uninhabited waste, the dreaded abode of the tiger, and other ferocious wild animals. The soil of Bengal is a blackish mould, chiefly composed of clay and sand, abounding with vegetable and animal substances, and often impregnated with saline matters.

Inundations.—The inundations which form so striking a feature in the natural history of Bengal, and are so essential to the produce of the soil, arise from the torrents of rain which fall in the lower districts of the province, and from the melting of the snows near the distant sources of the great rivers. About the end of April the waters begin to rise, and by the end of July all the low parts of the country in the vicinity of the Ganges and Burrampooter are overflowed, when nothing is to be seen above the liquid surface but villages and trees, for an extent of more than a hundred miles. The inundation is stationary for some days previously to the middle of August, after which it begins to subside, and in October the land, highly fertilized, is ready for culture.

Agriculture.—Rice, which forms the principal food of a large proportion of the natives, is very extensively cultivated; but wheat and barley grow in some districts; and Indian corn, millet, and a great variety of pulse, are also raised. The sugar cane, poppies for the extraction of opium, mulberry trees for rearing the silk worm, tobacco, cotton, and indigo, are also objects of culture. But the culture is extremely imperfect; little skill or attention appears in the preparation of the land; the implements of agriculture are rude, and the operations are slow and awkward.

Natural productions.—All the rich fruits of tropical regions are abundant in Bengal; various kinds of excellent timber are produced, and applied to domestic purposes or the arts; and some of the more valuable medicinal drugs form important commercial commodities. The nature of the climate, and the secure retreats which the country affords, are highly favourable to the multiplication of every description of animals.

Inhabitants.—Of the population of Bengal, no certain estimate has been formed; but, according to a statement, to which little accuracy can be attached, it contains nearly 15,000,000 inhabitants, or about one half of the population subject to the British government in India. They are distributed in forty or fifty large towns, and a great number of populous villages. Calcutta, comparatively a modern town, is the capital of the British settlements in the East, and the residence of the governor-general. The native Hindoos compose four-fifths of this vast population. The rest are Moguls, of Tartar origin, who conquered the country in the fifteenth century. The Mogul inhabitants have an olive complexion, and resemble Europeans in the general cast of their features. They profess the Mahometan faith, are fierce enemies of the Hindoo idolatry, and, in spite of the restraining influence and power of the East India Company, express their abhorrence by persecution and bloodshed. The native tribes are the followers of Brahma. They are slender and handsome in their persons, their complexion is dark-brown or yellowish, and the hair is black, long, and straight. The practice of shaving the head is common; a piece of linen or cotton thrown round the middle is all the clothing of the lower classes; but the higher ranks wear turbans, and a dress of white cotton, which covers the whole body.

Manufactures.—Like other Asiatics, the natives of Bengal are distinguished for their manual dexterity in mechanical arts. With the simplest apparatus they produce the most beautiful fabrics of all kinds of cotton and silk goods; and the same delicacy of hand is not less conspicuous in the nicer and minuter operations of working in metals, and fabricating utensils and trinkets for domestic use or ornamental purposes.

Commerce.—The navigable rivers of Bengal afford great facilities for commercial intercourse with the interior regions of India. A great trade in silks, cotton goods, sugar, indigo, and medicinal drugs, is carried on with Agra, Delhi, and Thibet. Of the extent of this trade some conjecture may be formed, when it is stated, that 30,000 boatmen are employed in inland navigation. The boats, or *budgeroes*, are variously constructed, according to the nature of the stream which they navigate. They draw from four to five feet of water; and they are sometimes fitted up with spacious cabins for the accommodation of passengers. At different periods of the year, and in different states of the river, the progress of the boats varies from 17 to 20 miles, when dragged against the stream, and proceeding with the current at the rate of 40 and 70 miles a day.

The maritime trade of Bengal is also considerable, and, in the hands of natives or Europeans, extends either directly or more circuitously to almost all the islands and countries in the eastern quarter of the globe. The Armenians, who have been long celebrated for their sagacity and success in mercantile affairs, enjoy no small portion of this trade.

European settlements.—In the beginning of the 17th century the English established their first settlement in Bengal, at the town of Hooghly; but in 1689 it was removed to Calcutta, 26 miles down the river; and after numerous conflicts in the field with the Mahratta states and the native princes, they obtained in 1765 the supreme government,—an era which has been justly regarded as highly favourable to the great mass of population, which is now under the equal protection of British authority. The French, Dutch, and Danes, had formerly settlements in the same province.

BENIN, a district or kingdom of Guinea in Africa, has, for its boundary on the west, part of the gulf called by mariners the *Bite of Benin*, and the Slave Coast and Congo on the south, extends about 600 miles from east to west; is in general a low, flat country, covered with woods, part of which is intersected by rivers and lakes, and part is entirely destitute of water; and yields in great profusion most of the vegetable productions of tropical regions, as well as the various birds, quadrupeds, reptiles, and insects, which abound in warm countries. Indian corn, yams, and bananas, are cultivated as the chief food of the inhabitants. The climate is extremely insalubrious; thick fogs are very prevalent; and tremendous storms of thunder and lightning are not rare.

The principal labours of the field, as well as domestic concerns, and even it is said, in some erroneous accounts, the handicraft arts, are assigned to the women. The character which has been drawn of the inhabitants seems to be altogether inconsistent with itself. They are represented as friendly, hospitable, and generous; their institutions, it is asserted, breathe the purest spirit of humanity; the aged and infirm are gratuitously supported; no one is allowed to pine in want, and beggary is altogether unknown; but, on the other hand, they are described as indolent in the extreme, and, unless they are compelled by poverty, never submit to any kind of manual labour. From all this it appears that they are a lazy barbarous people, and their reputed virtues only exist in the partial narratives of credulous travellers. The Portuguese had formerly settlements in this country, and the slave trade was at one time considerable.

Benin is also the name of the capital of the country, and the residence of the king. The mud houses are covered with reeds or leaves; the streets are spacious, the market is well furnished with the productions of the country, and with European merchandise, for which they are to be exchanged; and the compass of the whole town is stated at four miles.

BENTLEY, Richard, a learned English critic, was a native of Yorkshire, and was born in 1662; was initiated in classical literature at the free school of Wakefield, and in his fifteenth year was admitted a student in St John's college, Cambridge. In the prosecution of his studies he was remarkable for assiduity and industry, of which a singular instance is recorded in the laborious undertaking which he executed of arranging alphabetically every word of the Hebrew bible, and marking in five separate columns, the various interpretations of the same words in the Chaldee, Syriac, Vulgate, Septuagint, and Latin bibles. The production of a thick quarto volume was the result of this mighty task; and another volume of equal magnitude was occupied with the emendations and various readings of the Hebrew text, collated from ancient manuscripts. After four years residence at the university, he was employed for some time in teaching a public school, and afterwards as a private tutor; and having been ordained to the priesthood, he was the first preacher appointed to deliver the lecture established by Mr Boyle in support of the doctrines of natural and revealed religion. His discourses on this occasion were published.

The appointment of Dr Bentley, in 1693, to be keeper of the royal library at St James's, in which his zeal and industry soon became conspicuous, was the prelude to more lucrative offices and higher distinctions; for, in 1700, he was raised to the mastership of Trinity college, Cambridge; soon after preferred to be archdeacon of Ely; and, in 1716, was nominated Regius professor of divinity in Cambridge.

From two events in his life, which obtained considerable notoriety, it may be presumed that Dr Bentley was not possessed of the most conciliating or courteous manners. Some severe remarks, delivered in a contemptuous tone, which escaped from the learned, and perhaps somewhat arrogant critic, on an edition of Phalaris published by the honourable Charles Boyle, produced a violent literary squabble, in the course of which it is generally admitted that Bentley proved the epistles ascribed to Phalaris to be spurious. The other incident alluded to, which was more serious in its consequences, was a dispute with his college, on some points of reformation, which provoked hostility from those who were immediately interested, and afterwards on a demand for additional perquisites, which was also resisted, and terminated in deprivation from all his privileges, honours, and degrees in the university. But an appeal to the king, and a reference to the council and the court of King's Bench, procured his re-instatement in all his offices and privileges, of which he enjoyed the undisturbed possession to the end of his life, which closed in the year 1742, when he had reached the venerable age of 81.

Two comedies of Aristophanes, Fragments of Menander and Philemon, editions of Terence, Phædrus, and Milton, and an edition of Horace, published in 1711, which acquired for him great celebrity, are the fruits of Dr Bentley's critical skill. He had circulated proposals for an edition of the Greek Testament; but the remarks of his literary antagonist, Dr Middleton, determined him to relinquish the undertaking, and return L.2000 of subscription money.

BENZOIN, a gum resin obtained from a species of styrax. See CHEMISTRY.

BERAR, a large and centrical province of the Deccan, in India, which extends from the 19th to the 22d degree of north latitude, is about 230 miles in length, and 120 miles in breadth, and has Allahabad for its boundary on the north, and Aurungabad and the Godavery on the south. The surface is in general elevated and hilly, and abounds in strong holds; it is well watered by numerous streams, of which the Godavery, Tuptee, and Poornah are the chief; is but thinly inhabited and sparingly cultivated, although in some places the soil and climate are extremely favourable for the production of wheat, barley, rice, sugar, cotton, opium, and silk, and the bullocks are reckoned the best in the Deccan.

The population is supposed not to exceed 2,000,000, of which one-tenth are Mahometans, and the rest are the followers of Brahma. Three-fourths of the province belong to the territories of the Nizam, and the remainder is tributary to the Mahrattas. Among the lowest tribes of Berar a singular kind of suicide prevails. In return for benefits solicited from idols, a solemn vow of self-destruction is made, and the supposed successful votary in the fulfilment of it throws himself from a precipice in the mountains between the rivers Tuptee and Nerbuddah. In the time of an annual fair near this spot, eight or ten enthusiasts fall victims to this superstition.

BERBERIS, the BARBERRY, a genus of plants belonging to the Hexandria class, one species of which, *vulgaris*, is a native of most parts of Britain.

BERBICE, a British colony in Guiana in South America, which derives its name from the river along whose banks it extends for 300 miles. The breadth is from 40 to 45 miles. The shores are low and swampy; the country continues flat far inland, and is covered with thick forests, in which trees of enormous magnitude shoot up. Like other intra-tropical climates, the seasons in this district observe a pretty regular succession of wet and dry weather.

Berbice is the principal river; it flows from south to north, and discharges itself into the Atlantic ocean; it is a mile broad at its influx into the sea in the 6th degree of N. latitude; but the entrance is partly closed by Crab island, so designated from the profusion of land-crabs which it produces. The Berbice is navigable for ships of considerable burden 200 miles into the interior; but a bank of sand opposes their approach, so that only small vessels can enter, and ships from Europe load and unload at Demerary. The Canjè, which falls into the river Berbice, about a mile from the sea, admits the navigation of small vessels for a course of 30 miles. In some parts of the colony canals have been cut to facilitate the conveyance of produce by water-carriage.

The population of Berbice, in 1811, is stated at 550 whites, 240 persons of colour, and 25,169 negroe slaves. Sugar, coffee, cocoa, cotton, anotta, and indigo are the principal productions. The only towns are Old and New Amsterdam; the former is about 50 miles up the river Berbice; the latter has risen chiefly since the colony became subject to Britain, and occupies the banks of the Berbice near the confluence of the Canjè; it is the seat of the colonial government; and except the public buildings, which are of brick, the houses are usually constructed of wood.

Berbice was settled by the Dutch in 1626: it fell under the dominion of Britain in 1796; was restored to the Dutch at the peace of Amiens; but in 1803, it was again reduced by British troops, and has since acknowledged British authority. But, by a legislative enactment in 1816, the Dutch colonists, who are subjects of the king of the Netherlands, have certain privileges of supplying their estates with necessaries only, and not for the purposes of trade, from the parent country, and of exporting their produce to the Netherlands; but this limited trade is to be conducted in Dutch ships.

BERCHTOLSGADEN, a principality which, along with Salzburg, forms a province of the Austrian empire, includes an area of nearly 200 square miles, and above 200,000 inhabitants. It is chiefly a mountainous district, and affords a considerable revenue from the salt-mines.

Berchtolsgaden is one of the chief towns, and contains about 3000 inhabitants, who are chiefly employed in the manufacture of wooden, bone, and ivory toys.

BERG, a duchy in the circle of Westphalia in Germany, is a mountainous district, which covers more than 1200 square miles of surface, and includes a population equal to 610,000. That part of the duchy which stretches along the Rhine has a fertile soil, which produces abundance of corn; the more elevated vallies afford excellent pasture; the vine thrives on the hills, and the mountains are clothed with thick forests. Mines of lead, iron, and coal are wrought; and swords, knives, and other instruments of iron and steel, ribbons, and various kinds of cloth, are the principal manufactures. Dusseldorf is the chief town. Berg, with Cleves, was constituted in 1806 a grand duchy by Bonaparte, and Murat was nominated grand duke.

BERGAMO, the capital of the district of Bergamasco in Italy, stands on several hills, and is strongly fortified, contains numerous churches and convents, and about 30,000 inhabitants, who enjoy a considerable trade in silk and woollen stuffs, and have been long celebrated for the excellence and beauty of their serges and tapestry. A fair held at the feast of St Bartholomew draws together merchants from different parts of Italy, Germany, and Switzerland.

BERGEN, a sea-port town, and capital of the province of Bergnhuys in Norway, is arranged in the form of a crescent round the head of the bay, is defended on the land side by lofty mountains, and by forts and batteries towards the sea, and contains about 16,000 inhabitants. The harbour of Bergen is reckoned one of the finest in Europe. Timber, fish, hides, and tallow are exported, and corn and foreign merchandize are the principal imports. The public buildings are constructed of stone, but the greater part of the town is built of wood, from which it has been subjected to dreadful calamities by fire. Three terrible conflagrations almost reduced it to ashes in the course of the eighteenth century.

BERGEN, the capital of the island of Rugen, belonging to Swedish Pomerania, stands in the centre of the island; the population exceeds 15,000; and at several fairs, which are held annually, the trade in linen and cattle is considerable.

BERGEN-OP-ZOOM, a beautiful town and strong fortress, stands on a rising ground on the banks of the river Zoom, near its junction with the Scheldt, in the middle of a flat, marshy country, and was formerly one of the frontier towns of Dutch Brabant.

Founded in 1287, by John I. duke of Brabant, when he divided the barony of Breda, it was erected in 1535 into a marquisate by the emperor Charles V. In 1689 it was regularly fortified by the celebrated Cohorn, and has ever since been considered one of the strongest fortresses in Europe. Regarded as a place of great importance, Bergen-op-zoom has been always a point of attack amid the wars and revolutions which have so often distracted that part of the continent. Sieges and battles furnish the chief incidents in its eventful history. In the Dutch revolutionary war, it was the scene of many bloody conflicts; and in 1747 it fell into the hands of the French, owing, it has been alleged, to sudden surprise or secret treachery, rather than to the military skill of the commanders, or signal valour of the troops. But one of the most memorable assaults which Bergen-op-zoom had yet witnessed, took place on the 8th of March 1814, by the British troops under the command of Lord Lynedock. The attack was made at ten o'clock at night; a party of the troops made their way into the centre of the town; but being unsupported by the divisions, which had been retarded in their approach by unforeseen difficulties, they were compelled to lay down their arms, and surrender prisoners of war. The result of so bold and hazardous an exploit, even if it had been successful, could not fail to be disastrous to the assailants. Several officers of rank, and a considerable number of men, fell in the conflict. But it is admitted that the plan of attack was judiciously arranged, and the bravery of the troops in its execution was never surpassed. Bergen-op-zoom is 18 miles north-west from Antwerp.

BERGERAC, a town of the department of Dordogne in France, occupies a fine situation in a plain on the banks of the river Dordogne, by which it is traversed, and contains more than 8000 inhabitants, who are employed in forges, founderies of cannon, and the manufacture of paper in its vicinity. The revocation of the edict of Nantes drove 40,000 protestants in this town and the surrounding territory to seek an asylum in foreign countries, and to enrich other nations by their arts and industry.

BERGMAN, Sir Torbern, an eminent chemical philosopher, was born at Catharineberg, in West Gothland in Sweden, in 1735. In his boyish years he was remarkable, it is said, for a froward, petulant, and mischievous disposition, amusing himself with the destruction of whatever came in his way by committing it to the flames, and delighted with the malicious gratification of seeing the vexation and disappointment of his relations and friends; and neither admonition nor punishment had any influence in restraining this singular propensity. But as he advanced to maturer years, this pernicious habit gave way to serious study and mental improvement. Having completed the elementary part of his education, he entered the university of Upsal in his 17th year, and soon discovered the most devoted attachment to mathematical and physical science. Destined probably by his friends for some department of the active business of life, he was prohibited by the command of a relation with whom he resided to read books of an abstract and profound character, such as *Euclid's Elements*, and *Newton's Principia*. But they were his favourite authors; and seemingly yielding to the injunction, he concealed them from his guardian, devoted the hours of repose to such severe study that his health was injured, and was compelled to relinquish for a time his academical pursuits, and retire to the country.

The restoration of his health in 1754, permitted him to resume his studies at Upsal, on which the splendid reputation of Linnæus at that time threw so bright a lustre. With the example of that great man before them, all those who were ambitious of learned fame, pursued his path, and devoted themselves to some department of natural history. Attracted by these alluring studies, Bergman directed his researches chiefly to insects, and to the progressive changes of their varied existence; and the curious discoveries which rewarded his industry, excited the admiration, and secured to him the esteem and friendship of the illustrious naturalist.

In 1761 he was nominated joint professor of mathematics and natural philosophy. Previously to his appointment he had published memoirs on the *Rainbow*, on the *Origin of Meteors*, and on the *Twilight*; and during the period of five years which he held that chair, he was much occupied in disquisitions on the *aurora borealis*, and other electrical appearances. Astronomy also obtained some share of his attention, for he observed the transit of Venus in the year 1761. The resignation of Wallerius, the celebrated professor of chemistry and mineralogy at Upsal, opened a new path to the ambition of Bergman, and gave a new direction to his pursuits. He appeared as a competitor; but his opponents and their friends started a formidable objection, that he was not qualified by his previous studies to undertake the office. Conscious that the objection was not altogether groundless, with a noble ardour he determined to adopt the best means of removing it; and for this purpose he examined the properties of alum, and drew up a memoir on the subject of its preparation, and the most economical method of procuring that salt. All parties were astonished; his friends hailed it as a triumph and earnest of success, and his adversaries laboured to undervalue its merit. After a severe contest, in which the interference of the prince royal of Sweden, chancellor of the university, was required, Bergman, now in his 32d year, was, with his approbation, appointed to the vacant chair.

Entering with enthusiasm on the duties of his new office, he improved and enlarged the laboratory in the university; disposed in a commodious manner all parts of his chemical apparatus, and the different instruments employed in the arts; re-arranged his own cabinet of minerals along with those of his predecessors; and added the most approved works on chemistry, and the kindred arts, to his collection. The method which Bergman adopted in conducting his researches was peculiarly favourable to the advancement of that science which he was now destined to cultivate and adorn. Dismissing every preconceived theory, he established all his conclusions on accurate observations, and precise results of experiments, judiciously instituted and carefully executed. In all his investigations he was guided by the true principles of inductive philosophy.

The acid property of fixed air was among the first discoveries in the brilliant career of Bergman. To the list of acids he added the oxalic or acid of sugar, which is obtained by the distillation of sugar with nitric acid, the phosphoric, and the molybdic and tungstic, two metallic acids. The earth of barytes, and the characters of some of the other earths were more distinctly discriminated; and in a memoir on crystallization, he derives all the variety of crystals from a simple primitive form. Among the chemical labours of Bergman may be enumerated his excellent analysis of mineral waters, of volcanic products, of precious stones, and of various metallic substances—his ingenious researches into the nature of malleable iron, cast iron, and steel,—and his valuable tables of elective attractions.

The fame of Bergman, which had reached the king of Prussia, the great patron of learning and of learned men, procured for him, in 1776, a pressing invitation from that monarch to fix his residence at Berlin, and to join the celebrated band of literary and scientific characters which adorned his capital. He declined the flattering offer from a grateful feeling of the honours and distinctions which he enjoyed in his own country, although a warmer climate promised to be beneficial to his enfeebled constitution. He had long been afflicted with severe headache and palpitation of the heart. The aggravation of these complaints forced him to relinquish his studies, and in the hope of relief he undertook a journey to Medwi, to have the benefit of the mineral waters; but his strength was exhausted, and he died soon after his arrival in 1784, when he had reached the 50th year of his age. Bergman was not only a member of the academies of his native country, but was admitted into almost all the learned bodies of Europe. To honour his memory the academy of Stockholm ordered a medal to be struck as an expression of regret for the loss which science had sustained by his death; and during his life he had been raised by his sovereign to the dignity of knighthood. The principal works of Bergman,—*his Chemical Essays*,—his *Physical description of the Earth*,—*Essay on the Utility of Chemistry*,—*Thoughts on a Natural System of Minerals*,—*On the Elements of Chemistry*,—and *On the Progress of Chemistry*,—have been translated into French or English, or into both languages.

BERING'S STRAITS. See Beering.

BERKELEY, George, a celebrated metaphysical writer, and bishop of Cloyne in Ireland, was born at Thomastown in the county of Kilkenny in that kingdom, about the year 1684, and was descended from the noble family of Berkeley. The elementary part of his education was conducted at the school of Kilkenny, the same seminary in which Swift, a few years before had been initiated; and in his 15th year he was admitted a student in Trinity college, Dublin, in which he obtained a fellowship in 1707. Berkeley appeared as an author in early life. He had scarcely passed his 20th year, when he published an ingenious essay on *Arithmetic*; and, in 1709, he presented to the world a more celebrated production, under the title of a *New Theory of Vision*, from the consideration of which he concludes that magnitude as it is perceived by the touch, is essentially different from magnitude as it is discovered by the eye. The diversity of result between the notions derived from the senses of touch and sight, it is supposed may have led the ingenious author to adopt the opinion, that the objects of human perception are mere ideas of the mind, altogether independent of material substances. This doctrine was fully developed in his *Principles of Human Knowledge*, in which he denies the existence of every kind of matter, and asserts, that 'all those bodies which compose the mighty frame of the world have not any subsistence without a mind.'

In the year 1712, some of the political sentiments in three sermons which he published, and which had been delivered in the chapel of his college, in support of the doctrine of passive obedience, brought against him a charge of Jacobitism, and for a time retarded his preferment. But he had the good fortune afterwards to obtain the patronage of the prince and princess of Wales, who succeeded to the throne as George II. and queen Caroline. About the same time he produced another work, *Three Dialogues*, &c. in defence of his doctrine of Immaterialism, and through the good offices of his countrymen, Dr Swift and Sir Richard Steele, he became the associate of Addison, Arbuthnot, and Pope, and formed one of that bright constellation of men of genius which then adorned English literature. He was a contributor to the Spectator and Guardian.

In 1713, Dr Berkeley accompanied the Earl of Peterborough, in the capacity of chaplain and private secretary, on an embassy to Sicily and Italy; and on his return to England in the succeeding year he undertook a more extensive tour through Europe. After various disappointments he was nominated to the deanery of Derry in 1724; and about the same time the death of Mrs Vanhomrigh, the celebrated and unfortunate Vanessa of Swift, left him in possession of the unexpected bequest of one half of her property, amounting to L.4000, for which he seems to have been indebted to his agreeable manners and distinguished character, for it is said that he had been only once in her company.

The benevolent scheme of converting the American Indians to Christianity, by erecting a college in Bermudas for supplying the churches in the plantations with proper teachers, had for some time occupied the mind of Dean Berkeley; and in 1725 he published his plan in London, and offered to resign his rich benefice, and to accept of the moderate annual salary of L. 100. Three junior fellows of Trinity college, Dublin, eager to second his noble and disinterested efforts, declared their willingness to resign their livings and to accept of L.40 a-year. The plan of the institution was at last approved of; a charter was granted for erecting a seminary, to be called St Paul's college, in Bermudas, and to be composed of a president and nine fellows, who were bound to maintain and educate Indian children at L.10 a-year; and for the establishment and support of the institution L.20,000 were voted, and one-half of the sum was immediately advanced. The dean and his associates, who were permitted to retain their livings in Ireland till the whole sum was paid, crossed the Atlantic and arrived at Newport in Rhode Island, contracted for the purchase of lands on the contiguous continent, and, after many tedious delays and much fruitless expectation, the remaining L.10,000 was never paid; and, after seven years of his life spent in promoting the establishment, with a considerable diminution of his private fortune, he was compelled to return to Europe mortified and disappointed at his failure.

In 1732 the *Minute Philosopher*, one of his most popular and most admired productions appeared. The object of this work, which is drawn up in the form of dialogue, is to refute the tenets of a free-thinker, who is represented in the various characters of atheist, libertine, enthusiast, sceptic, &c. At the recommendation of queen Caroline, whose favour he still retained, he was preferred to the see of Cloyne, and was consecrated bishop in 1734, on which occasion he declared that he would never accept a translation, and to this resolution he firmly adhered, even when the offer of a more valuable benefice was in his power. He resided constantly in his diocese, where he was distinguished by pastoral vigilance and hospitality; and by promoting at once the temporal and spiritual welfare of all ranks, greatly endeared himself to his flock. While his health permitted he preached regularly, and his sermons were always extemporaneous.

Besides some philosophical disquisitions connected with his former inquiries, bishop Berkeley published some works on municipal and prevailing political subjects of the day; and it is not a little to his praise, that in consequence of a letter addressed, in 1749, to the Roman Catholic clergy of Ireland, he received the thanks of that body, by whom he was characterised as " the good man, the polite gentleman, and the true patriot." His *Siris*, a treatise on the virtues of tar-water, became a popular work, and was the means of introducing that substance as a kind of universal remedy.

In 1752 he determined to retire with his family to Oxford, to superintend the education of his son; but as he was strongly impressed with the obligation of residence in his diocese, he endeavoured to exchange his bishopric for some benefice in Oxford. Failing in this plan, he applied to the secretary of state for permission to resign his bishopric; but the king declared, when the petition was presented, that he would not accept the resignation, and that the bishop had full liberty to choose his own residence. Before his departure from Ireland, he directed an income of L.200 a-year from some part of his lands to be distributed among the poor. His residence at Oxford was of short duration. On Sunday evening the 14th January 1753, while one of his family was reading a sermon of Dr Sherlock's, he expired in a moment without a groan or convulsive pang. The fine eulogium of bishop Atterbury, after the first conversation with this excellent prelate, " so much understanding, so much knowledge, so much innocence, and such humility, I did not think had been the portion of any but angels, till I saw this gentleman"--and the high encomium of Pope, who ascribes

"To Berkeley every virtue under heaven,"

shew in what estimation his character was held by his cotemporaries; and the details of his life, with the perusal of his works, will enable posterity to judge of the talents of the philosopher and the virtues of the man.

BERKSHIRE, an inland county of England, has the Thames and Oxfordshire for its boundary on the north, Buckinghamshire on the east, Surrey and Hampshire on the south, and Wiltshire on the west, and includes an area of nearly 780 square miles, or more than 476,000 acres. Berkshire admits of four natural divisions, 1. The White-horse Vale, which is bounded on one side by the Thames and on the other by the White-horse hills, a ridge of elevated land, which is a continuation of the Chiltern range, 2. The Chalk-hills, which traverse the lower part of the county: 3. The vale of Kennet; and, 4. The Forest division, which stretches across the country from the east of the river Loddon to Old Windsor.

The solid strata of Berkshire are composed of chalk, which abounds with animal remains; extensive beds of sand and gravel are common in many places; a coarse kind of fuller's earth is sometimes met with, and pipe and potters' clay is dug out for the manufacturer. The peat-earth of Berkshire, in which gypsum predominates, has been celebrated as an active manure when converted into ashes. The prevailing soil is a calcareous loam; in some places it is gravelly, but is generally fertile and productive. In the southern parts of the county the gravel and clay soil is remarkable for its sterility.

The Thames, which is a natural boundary to Berkshire for more than 100 miles, the Kennet, the Loddon, the Ocke, the Lambourn, and the Auborn, are the principal rivers, and some of them abound with excellent fish. Berkshire has the advantage of inland navigation from the Wiltshire and Berkshire canal, and the Kennet and Avon canal, which latter is carried from Newbury to Bath, a distance of 60 miles.

The population of Berkshire was estimated, in 1700, at 75,000; in 1801 at 109,215; and in 1811 at 118,277. The chief towns are Abingdon, Reading, which are both considered as county towns, Farringdon, Hungerford, Ilsley, Lambourn, Maidenhead, Newbury, Oakingham, Wallingford, Wantage, and Windsor. Wheat and barley are the chief corn crops of this county. A great deal of malt is manufactured for the supply of the London and Bristol market. Some extensive farms are laid out for the production of the dairy. Cheeses in the form of the pine-apple are highly celebrated for their fine flavour, and bring a superior price in the market. Numerous flocks of sheep are reared on the hilly pastures, and the excellence of its breed of hogs is well known. A considerable extent of the surface of this county is covered with woods; but the banks of the Thames, the vale of Kennet, and Windsor forest, are chiefly remarkable for forest timber.

The manufacture of cloth, which flourished in some of the towns of Berkshire in the 17th century, is now unknown. Beside two paper-mills, one of which is on a large scale, the manufacture of serge at Newbury and of coarse sacking at Abingdon only merits notice. The rolling and hammering of copper for bolts and sheathing for ships, as well as for foreign trade and domestic purposes, at the Temple-mills, form an extensive concern, in which 1000 tons of copper have been sometimes manufactured annually.

BERLIN, the capital of Brandenburgh, and of the Prussian dominions, is one of the finest towns of Germany, stands on the banks of the Spree, which falls into the Havel, a tributary stream of the Elbe, and is more than four miles long and three miles broad. The streets are generally regular and broad; several of them exceed a mile, and Frederick Street is more than two miles in length, and the houses are constructed with freestone or brick, and are usually two stories in height. The squares are spacious, and many of the public buildings are magnificent edifices; among which are enumerated the royal palace, which is four stories high, has some of the apartments adorned with the richest tapestry, and many pieces of furniture of solid silver, and includes a library of 100,000 volumes, of which number 500 bibles, and among them, it is said, is the bible which Charles I. of England used when he was brought to the scaffold; the arsenal, which is one of the grandest structures of the kind in Europe, is adorned with a statue of Frederick I. which is greatly admired; and the royal stables, which are equally spacious and magnificent, have two courts with a covered menage between them.

Berlin is also adorned with other splendid edifices, such as the opera-house, the hall of the academy of sciences; the hospital of invalids, in which 1000 officers and soldiers are lodged and maintained; various palaces and numerous churches. Some of the bridges over the Spree, and some of the large squares are adorned with splendid statues of bronze or marble. The neighbourhood of the city is finely diversified with canals, vineyards, and beautiful villas; and the parks, which are agreeable places of resort, are much frequented on Sundays and holidays. The institutions for the cultivation of literature and science, or destined to charitable purposes, are numerous.

The population of Berlin, including the garrison, which amounts to about 30,000, is estimated at 140,000. The manufacture of silk, woollen, cotton, and linen cloth is extensive; in 1799, 7014 looms were employed, and the whole number of artisans exceeded 14,000.

BERMUDAS, or SOMER ISLANDS, a group of islands in the Atlantic ocean, in north latitude 32° 35′, and between two and three hundred leagues from the continent of America. The whole number of these islands is about 400, extending over a space of 45, miles from north-east to south-west; but most of them are bare rocks, and very few are inhabited. Their discovery was accidentally made in 1527, by John Bermudas, a Spanish navigator, from whom one of the names is derived; but he neither landed, nor was any settlement made by his countrymen. Soon after, Henry May, an Englishman, was unfortunately shipwrecked on one of the larger islands; and having constructed a vessel of cedar-wood, an abundant production of these islands, he returned to Europe, and published an account of them, the first which had appeared. In 1609, Sir George Somers and some others, in a voyage to Virginia, as deputy-governors, had also the misfortune to be shipwrecked on the Bermudas. They reached America in vessels built of the native cedar-wood; and Sir George having returned to the islands in search of provisions for the colony in Virginia, died soon after his arrival, and from him they were denominated, Somers, or Summer's islands. His surviving companions returned to England; made a favourable report of their beauty and fertility; and induced the Virginia company, who claimed the property, to divide the whole into 120 shares, and to assign the right to the purchasers, who obtained a charter from James I. An expedition was fitted out in 1612; and 60 planters proceeded as adventurers, under a regular form of government, to form a settlement. In the course of a few years the Bermudas were crowded with inhabitants from England; some attracted by the exaggerated accounts of the fine climate, and some driven from their native country by the distractions and dangers which prevailed during the civil wars.

The principal islands are, Bermuda, Saint George, Saint David, and Somerset. Bermuda exceeds 30 miles in length, and is about two in breadth. The country is generally rugged and mountainous, but in many places the plains are covered with a fertile and productive soil. The Bermudas are divided into nine parishes, which include more than 12,000 acres. The white inhabitants in 1810 were estimated at 4755; the free persons of colour at 451, and the slaves at 4794, making the total population equal to 10,000; but it is supposed that the number of black and coloured inhabitants is under-rated. The government is similar to that of the West India colonies. The established form of religion is that of the church of England; but there is a presbyterian congregation, and another belonging to the methodists, which are supported by voluntary contributions.

Indian corn, tobacco, and a little cotton, are the chief vegetable productions which are objects of culture; and most of the West India fruits grow to perfection. Turtle is abundant on the coast, and is a valuable source of trade; and ambergris, of which large masses were collected by the early settlers, who entertained sanguine hopes that it would be a permanent acquisition, is occasionally met with in small quantities. Beside agricultural occupations, the inhabitants are employed in ship-building of native cedar-wood, in fishing, and in carrying salt from Turks island to America.

BERN, one of the largest cantons of Switzerland, is bounded on the east by the cantons of Uri, Underwalden, and Lucern; on the south by the lake of Geneva and the duchy of Savoy; on the west by Soleure and part of France; and on the north by Basle and the Austrian forest-towns. The length is estimated at 180 miles, and the breadth about 90 miles. The canton of Bern presents an extremely diversified surface; it is encompassed with lofty mountainous groups; and its extensive forests and spacious lakes exhibit altogether a great variety of picturesque scenery.

The population of the canton is variously estimated at 340,000 and 400,000, distributed in a number of considerable towns and many small villages. The plains are fertile and well cultivated, and the elevated regions afford excellent pasture to numerous herds of cattle. The manufactures of linen, woollen, silk, and cotton-stuffs, and coloured stockings are considerable; and, with cheese, butter, and horses, afford a valuable trade with the neighbouring districts.

BERN, the capital of the canton of the same name in Switzerland, stands on the banks of the Aar, and is nearly encompassed by that river. The streets are spacious and clean, the houses are nearly of the same height and uniformly built, and the town is adorned and refreshed by fountains, which are supplied with water from a branch of the Aar. The cathedral is a fine Gothic structure, which has been much admired. The population of Bern is estimated at 15,000, who are chiefly occupied in the manufactures already noticed in the description of the canton. Bern can boast of a number of literary and scientific institutions. It is 45 miles south from Basle, and 78 miles north-east from Geneva.

BERNERA, a small island belonging to the western islands of Scotland. See HEBRIDES.

BERNOULLI, JAMES, a celebrated mathematician, was the son of Nicholas Bernoulli, an active and respectable citizen of Basle, who held important offices in his native city, and was born at Basle in 1654. Nicholas Bernoulli left a family of eleven children; two of whom, James and John, distinguished themselves by the most profound geometrical investigations, and rose to the highest rank among the mathematicians of the eighteenth century.

James Bernoulli was destined for the clerical profession; but his strong inclination for mathematical studies withdrew his attention from every other pursuit, and he gave very early proofs of talents for those profound investigations by which he was afterwards so distinguished. Having visited different countries of Europe, he was elected professor of mathematics at Heidelberg; and at the end of three years was appointed to the same chair in the university of his native city. He died in 1705, when he had reached the 51st year of his age.

BERNOULLI, JOHN, a distinguished mathematician, was the tenth son of Nicholas Bernoulli, and was born at Basle in 1667. The early part of his education was conducted, first, with a view to commercial pursuits, and afterwards to qualify him for the practice of medicine. But with the example, and under the tuition of his brother James, his studies were directed to mathematical science, in which he acquired the highest reputation. He was first appointed professor of experimental philosophy in the university of Groningen; and, on the death of his brother, succeeded to the professorship of mathematics at Basle. He died in 1748, in the 81st year of his age. Of a family of nine children, three were professors; and Daniel, in mathematical genius, was not surpassed by his father and uncle.

BERNOULLI, DANIEL, a very eminent mathematician and natural philosopher, was the son of John Bernoulli, and was born at Groningen in the year 1700. He began early the study of mathematics, and gave unequivocal proofs of powerful talents in geometrical investigations. He prosecuted the study of medicine, first in his own country, and afterwards in Italy; but still mathematical pursuits occupied a large share of his attention. Being invited by the academy of St Petersburgh, he repaired to that city; and, greatly honoured and distinguished, he spent several years of his life in the imperial capital, till his declining health required him to seek for its restoration in a milder climate. In 1733 he returned to Basle, which was then his father's residence, and was elected professor of medicine and afterwards of physics. He died in 1782, in the 83d year of his age.

The sublime genius for mathematics which pervaded this remarkable family, presents a prominent feature in the history of the science. A minute detail of the profound researches and sublime investigations with which they were occupied, could not be interesting to the general reader. But the jealousy and rivalship which existed between the two brothers, and between the father and son, exhibit another feature in their lives less amiable but not less singular. Ambition for fame diminished the warmth of affection which had subsisted between the two brothers before they had acquired such distinguished reputation; and a difference of opinion, about the solution of a mathematical problem, burst asunder the bands of friendship, and produced the most decided enmity. John Bernoulli entertained the same jealousy against his son Daniel. The first efforts of his youthful genius in the brilliant career which he was destined to run, were rudely repressed; and when he divided the prize with his father, for the best explanation of the variation in the inclination of the planetary orbits, the mortification of the latter was extreme, and terminated in bitter resentment and permanent hostility.

BERWICK, COUNTY, or Berwickshire, forms the south-eastern portion of Scotland; has the river Tweed for its boundary on the south, the German ocean on the east, East-Lothian on the north, and on the west Mid-Lothian and Roxburghshire, and is about 30 miles long, and about 19 miles at its greatest breadth. Berwickshire is traversed at its northern extremity by a lofty ridge, the Lammermoor mountains, which, stretching westward from the promontory of St Abb's head on the east coast, preserves an elevation of nearly 1000 feet, and in one place rises 1500 feet above the level of the sea. The prevailing rocks are, the grey wacken of mineralogists; and of the schistose variety, which is also met with, some is dug out for the purpose of roof-slate. Extensive beds of red sandstone skirt the eastern coast of the county; and a large mass of breccia, or plumb-pudding rock, constitutes the northern promontory of Eyemouth-bay. The Tweed winds its majestic stream along the margin of Berwickshire for a course of forty miles; but within its borders, the Whitadder and Blackadder, which mix their united waters with the Tweed near Berwick, and the Leader and the Eden, of inferior magnitude, are the principal rivers.

The population of Berwickshire, which in 1755 was estimated at nearly 25,000, amounted in 1801 to 30,621, and in 1811 to 30,779. Greenlaw the county town, and Dunse, with a population exceeding 3000, Coldstream, Lauder, and Eyemouth, are the chief towns. The manufacture of paper, the salmon fishery on the Tweed, the white fisheries on the east coast for the supply of the Edinburgh market, and the export trade from Eyemouth, with the importation of coal, lime, and other commodities for domestic consumption, beside the labours of agriculture, afford the principal employment to the inhabitants. The modern agricultural improvements in Scotland were first introduced into Berwickshire, which still takes the lead in the most approved system of alternate husbandry. The elevated districts of the Lammermoor hills afford excellent pasture to numerous flocks of sheep.

BERWICK-UPON-TWEED, stands on the northern bank of that river, about a mile from its influx into the German ocean; from its peculiar position was often a disputed post between the rival nations of England and Scotland, but is now annexed to England, with a small territory of four or 5000 acres, and is governed by English laws. Berwick was fortified by the English early in the sixteenth century; and the remains of fortifications of a still older date, erected by the Scotch, are still visible. Few of the streets are spacious; some of them are steep and narrow; and the bridge of sixteen arches, which crosses the Tweed, and can lay claim to some antiquity, is also narrow and incommodious.

The population, which in 1801 was estimated at 7187, had increased, in 1811, to 7746. The municipal establishment is assimilated to that of English boroughs. The Tweed is navigable to the town; but a bar at its mouth excludes vessels of large burden. Timber, iron, and flax are imported from the Baltic; grain, in considerable quantities, from the neighbouring districts, and wool, and eggs, and salmon preserved in ice, for the London market, are exported. It is said that L.20,000 worth of eggs have been shipped off in a single year. The rent of the salmon fishery exceeds L.10,000 annually. Berwick is 54 miles from Edinburgh, and 335 from London.

BERWICK, NORTH, a royal borough and seaport town of the county of Haddington, or East-Lothian, in Scotland. The harbour admits small vessels, and some grain is exported. The population is about 1600. The ruins of the castle of Tantallon, the ancient residence of the powerful family of Douglas, form a striking object, on a precipitous rock, washed by the sea, two miles from the town; and North Berwick-law, in its immediate vicinity, is a conspicuous land-mark, and rises in a conical form to the height of 800 feet.

BERYL, a mineral substance ranked among precious stones, and belonging to the siliceous genus. See Mineralogy.

BESANCON, the capital of the department of Doubs in France, stands on the banks of the river which gives name to the department, and traverses the city. The town is walled, fortified, and well defended by a strong citadel. The houses are well-built of stone, the streets are long and spacious, and the churches and public buildings are fine structures. Numerous remains of Roman antiquity are still visible in the ruins of a triumphal arch and some other buildings. Encompassed with mountains, the vicinity of Besançon exhibits many picturesque scenes, and the warm baths near the town offer a luxurious enjoyment to the inhabitants. The population is between 20,000 and 30,000; and fire-arms, swords, and clocks are the principal manufactures.

BESSARABIA, a province of the Ottoman empire, which is bounded on the east by the Black sea and part of the Russian territory, on the south by the Danube, and on the north and west by Moldavia; in some places is extremely fertile, producing grain, hemp, and flax, and is celebrated for the excellence of its fruits and the superior quality of its wines. The salt obtained by spontaneous evaporation of the waters of some lakes in this province, furnishes a valuable commercial commodity, and affords a considerable revenue to the government.

BETA, the Beet, a genus of plants belonging to the Pentandria class.

BETEL, the *Piper betle* of Linnæus, is a native of India, and is extensively employed in eastern countries as a luxury.

BETHESDA, a pond or public bath near the sheep market in Jerusalem, which was famous for the cure of the diseases of those who bathed in its waters. According to the Scriptural account, an "angel went down at a certain season into the pool and troubled the water: whosoever then first after the troubling of the water stepped in, was made whole of whatsoever disease he had." On the subject of this pool much disquisition has been employed by divines and commentators; but it seems to be generally admitted, that the cures which were performed by it in the time of Jesus Christ, are to be ascribed to miraculous influence.

BETHLEHEM, a city of Palestine, which is famous as the birth-place of Jesus Christ; and because it was also the birth-place of David, king of Israel, it was called the city of David. The place is now reduced to the state of a village, but it has been adorned with religious houses and magnificent churches, and has long been the annual resort of numerous bands of pilgrims, who come from distant quarters to perform their devotions. The village of Bethlehem is seated on an eminence in a mountainous district, and is two leagues south-east from Jerusalem. Fruits, olives, and vines thrive well, and, from the latter a white-wine, which has obtained some celebrity, is obtained.

BETHUNE, Maximilian, de, Duke of Sully, a celebrated French general and politician, was born in 1560; entered in early life into the service of the king of Navarre, afterwards Henry IV. of France, and rose to the highest and most important offices in the state. In war, in finance, and in negotiation, Sully was always distinguished by prudence, vigour, and fidelity; for his eminent services he received the most substantial benefits, and was honoured with the most splendid distinctions; and it is not a little remarkable, that he enjoyed all this influence and power while he professed through life the reformed religion, although, from motives of conciliating contending factions, he recommended to his master, who had been also a Protestant, to embrace the Catholic faith. But his zeal and integrity in the management of public affairs were not equally appreciated by the successor of Henry; for on the assassination of that prince, in 1610, he withdrew from court into the retirement of private life, and died in 1641, when he had reached the 82d year of his age. The *Memoirs of Sully* is a well known popular work, of which an English translation has been long before the public, and contains a highly interesting narrative of French history for a period of 40 years, from 1570 to the death of Henry IV.

BETONICA, Betony, a genus of plants belonging to the Didynamia class.

BETULA, the birch-tree, a genus of plants belonging to the Monœcia class.

BEVERLEY, a town in Yorkshire in England, which contains more than 5000 inhabitants, has a considerable trade in malt and manufacture of leather, and is remarkable for its spacious market-place, which is adorned with a fine cross. The minster is an elegant edifice, decorated with monuments in commemoration of the noble family of Percy.

BEVIEUX, a village of Switzerland, which is famous for the salt springs in its vicinity. The rocks of which the mountains are composed, and from which the springs have their source, are a whitish gypsum, mixed with blue clay, impregnated with salt. The operations are conducted by shafts, galleries, and machinery for raising the brine to reservoirs on the surface. It is said that these salt-works yield an annual profit of L.3000. Bevieux is three miles distant from Aigle.

BEWDLY, a town of Worcestershire in England, derives its name from the French *Beaulieu*, signifying *beautiful place*, it is conjectured, from its charming situation on a declivity on the banks of the Severn; contains nearly 4000 inhabitants, who are engaged in the manufacture of malt and leather, and particularly for caps known by the name of Monmouth caps, and enjoys a considerable trade by means of the Severn.

BEY, or BEGH, the appellation of a Turkish governor of a province or city. Some of these officers, as the bey of Tunis, have, by power or usage, acquired sovereign authority, and their dependence on the Ottoman Porte is little more than nominal.

BEZIERS, a city of the department of Herault, in France, occupies a fine situation near the junction of the river Orbe with the great south canal; contains more than 14,000 inhabitants, who are engaged in the manufacture of cloth, silk stuffs, and brandy, and is celebrated for the remains of a Roman amphitheatre. The university of this place was established in the end of the 16th century.

BEZOAR, a peculiar concretion which is formed in the stomachs of animals of the antelope and goat kind, and was once famous as a remedy in many diseases. The name is derived from a Persian word, signifying *antidote against poison*, because it was also employed for that purpose. Bezoar stones were at one time in such high repute as to find a place in the list of medicines recommended by the colleges. But the nature of the substance, which modern chemistry furnishes the means of examining, shews that the effects were exaggerated, so that they are now neglected. The formation of the Bezoar in the stomach of the animal depends on a nucleus of straw, hair, the pod of a fruit, or some indigestible substance, round which concentric layers of secreted matter are deposited.

BHADRINATH, a small town and celebrated temple in the province of Serinagur, in the northern regions of Hindostan, which stands in a valley in north latitude 30° 43′. The town includes only twenty or thirty huts for the accommodation of the brahmins during their visit in the time of the annual pilgrimage. The sacred temple, to which a supernatural origin is ascribed, rises in the form of a cone, with a small cupola, surmounted by a copper roof, a golden, or gilt ball, and spire, to the height of forty or fifty feet; the idol, three feet high, cut in black stone or marble, is richly dressed in gold and silver brocade; and in such veneration is this establishment held that it can number 700 villages among its possessions. But the offerings of pilgrims constitute a copious source of its revenue. A hot spring issues from the adjoining mountain, and supplies a warm bath; to numerous cold springs in the vicinity appropriate names and peculiar virtues are assigned, and from them, as his needs require, the pious visitant derives purification and comfort. The pilgrims are estimated annually at 50,000, and the greater proportion is composed of *fakirs*, or devotees, from the remotest corners of India. They assemble at the great fair of Hurdwar, and at its conclusion depart to the far-famed shrine. In the end of May 1808, masses of snow, 70 feet thick, were observed on the road to Bhadrinath, and the summits of the higher mountains are covered with perennial snow; a striking proof of the great elevation of a region in the 30th degree of latitude.

BIAFARA, a district of Africa, which is bounded on the south by the Rio Grande, and is included between the 11th and 12th degrees of north latitude. The inhabitants of this country are described as a peaceable inoffensive race, and from their chiefs, captain Beaver, who made an attempt a few years ago to establish a settlement on Bulama, obtained a grant of that island, of which some account may be seen in his *African Memoranda.*

BIBLE, from the Greek, and signifying *book*, is applied as a distinctive appellation to the scriptures of the Old and New Testament. See *Scriptures*, under RELIGION.

BIDEFORD, a seaport town of Devonshire in England, is a neat clean town, has a good harbour, which admits large vessels to the quay in its centre, a population of 3000, has a considerable concern in the Newfoundland fisheries, not fewer than 100 vessels of various sizes in the carrying trade, and exports oak timber and oak bark to Scotland and Ireland. The manufacture of earthen-ware, which is transported to Wales, is extensive.

BIDENS, WATER-HEMP AGRIMONY, a genus of plants belonging to the Syngenesia class.

BIENNE, formerly the capital of a district of the same name in Switzerland, and included at the French revolution in the department of the Upper Rhine, stands at the foot of mount Jura on the banks of the lake Bienne; has some manufactures of leather and printed cloths, and is remarkable for its abundant supply of water from numerous public fountains. The lake of Bienne is nine miles in length and two miles in breadth; the shores are adorned with castles, villages, and picturesque scenery; the island of Saint Peter, clothed with stately oaks, beeches, and chesnuts, is famous for a two months residence of the celebrated Rousseau, and is still the resort of strangers, particularly in the vintage season.

BIGGLESWADE, a town of Bedfordshire in England, occupies a fine situation in a valley on the banks of the Ivel, which is navigable at this place. is famous for its market for grain and pease, and has a population exceeding 1600, with a small manufactory of thread-lace.

BIGNONIA, TRUMPET-FLOWER, or SCARLET JASMINE, a genus of plants belonging to the Didynamia class.

BIJUGA, or BISSAGOS ISLANDS, a group of islands, of which thirteen are said to be inhabited, on the south-western coast of Africa, and separated from the continent by a deep channel, which stretches towards the island of Bulama, a course of more than 100 miles, and many of them are fertile and well wooded. Rice and fruits are produced in abundance. The natives are not more civilized than their continental neighbours; they are represented as treacherous and cruel; fond of war, no doubt for the sake of plunder; and bold and intrepid in enterprize. Beaver's *African Memoranda.*

BILBOA, the capital of Biscay in Spain, is situated on the bay of Biscay; the houses are lofty and well built; the streets are paved and clean; it is accommodated with docks for ship-building; and the promenade on the banks of the river, shaded with oaks and lime-trees, and bordered with warehouses and gardens, is highly celebrated. The population is about 15,000; and the trade with the mercantile countries of Europe is considerable.

BILE, a yellowish, bitter liquid, which is secreted in the liver, and seems destined to promote the digestion or assimilation of the food in the animal economy. See ANATOMY.

BILEDULGERID, *the Country of Dates*, or, by some, the *Dry Country*, a region in the northern quarter of Africa, which is included between the states of Barbary and Sahara, or the Desert. The interpretation of the name is characteristic of the climate, or of the productions of the country. The natives are Arabs, who profess Mahometanism; they are occasionally employed as mercenary troops by the neighbouring states; but they are oftener engaged in plundering excursions, or in hunting the ostrich, the flesh of which serves for food, and the feathers are a valuable commercial commodity. The fruit of the date, with a little dried fish, and camels milk and goat's flesh, constitute their ordinary fare.

BILL, a term of very general application; as, in commercial affairs, a bill of *lading* or of *exchange;* in law, a declaration in writing of some complaint or grievance; and in parliament, certain propositions which are offered for consideration, and, if approved, to be passed into a law.

BILLIARDS, from a French word signifying *ball*, a game which was invented by the French, and is played with ivory balls. See GAMES.

BILSTON, a town of Staffordshire in England, which is celebrated for its manufactures of japanned

Biography. and enamelled wares, and the numerous smelting furnaces, forges, and mills, for the reduction of the ores of iron, and for its conversion into various implements and utensils. The population is about 7000; and by means of inland navigation the communication with most parts of England is greatly facilitated.

BIOGRAPHY, is a species of literary composition which relates the actions and fortunes, and describes the characters of remarkable individuals. The term is derived from two Greek words, signifying *to write*, and *life*, and is properly used in contradistinction to history, the object of which is to record the origin, progress, revolutions, decline, and fall of states and countries.

As a nation is merely an aggregate of mankind on a larger scale than a family, and is no less liable to be influenced by the personal qualities and behaviour of its members, biographical sketches are necessarily blended in the narrative of events, and even with the discussion as to their causes, in which it is the duty of the historian to engage. Thus, it cannot be doubted, that the ambition of a Cæsar, or a Bonaparte, the patriotism of a Brutus, or the moderation of a Washington, the licentiousness of our Henry VIII. the hypocrisy of Cromwell, and the bigotry of the second James, materially affected the fortunes of their countries, and are consequently entitled to duly proportioned notice in the memoirs of their times. Biography, then, is, in this respect, obviously subservient to history, and indeed very often forms its chief interest and utility. Much there is, undoubtedly, to demand attention and exercise thought, in the progress of large masses of our species, from the savageness of the desert to the refinement and policy of civilized life, and through all the eventful periods of their prosperity, decay, and ruin. The miseries of their early condition,—the struggle between necessity and intelligence, by which our nature has been so much exalted,—the gradual accumulation of arts and devices, which enriched every present generation beyond the narrow conceptions of the preceding,—those new trials and perplexities, in which success itself so often involved the rising community, and which, by calling forth the evil principles of human nature, almost certainly prepared the means of its dissolution,—above all things, those repeated appeals to brutal force, and malignant or cruel inventions, by which the imperfections of all worldly policy are so dreadfully disclosed,—these events it is utterly impossible to contemplate with indifference, because, in addition to their magnitude and duration, by which they are calculated to occupy the imagination, they involve consequences, and suggest analogies, of importance to our own circumstances and conditions. But this reasoning and calculating spirit, on the whole, is little operative on the feelings. A reader finds some solace in the disproportion which he bears to the numbers concerned, and still more in the absence of all claim on personal sympathy. The prosperity and the sufferings of a large nation, more especially one which has long ceased to act its part on the theatre of the world, are to him merely abstract ideas, which have neither prototype nor foundation in his affections, and which he can readily, and almost at will, combine with any arrangement of causes which the information and skill of the historian authorise. As far as mere feeling is concerned, accordingly, he admits with equal facility the loss of twenty and of thirty thousand men in any celebrated battle, and cares not whether such a catastrophe occurred on the banks of the Euphrates or in the plains of Thessaly. In reality, he possesses no internal criterion of probability by which such extensive operations can be measured, and cannot experience a thousandth part of the emotions, sentiments, and prejudices which occasioned them, or operated during their continuance. Biography.

This puny effect of such relations, even in the hands of the greatest masters in historical composition, gives the lie to that universal philanthropy which it has sometimes been so much the fashion to admire, and demonstrates the actual selfishness and confined solicitudes of the human heart; and sufficient reasons are not wanting to palliate, if not to justify, this comparative apathy. What profitable dictate, what salutary result, it may be asked, can accrue to a private individual, at least, from the most authentic records of national affairs, beyond the gratification of rational curiosity, or the conviction which he can easily obtain elsewhere, or realize in his own experience, that uncertainty, vicissitude, and sorrow are by much the most considerable portion of human life, and that the gleams of comfort and happiness by which they are so sparingly checquered, give them but the greater power of afflicting? The knowledge thus acquired may enhance his consequence as a man of learning, and furnish topics on which the powers of description and the stores of memory may be displayed with enviable eloquence; but it is almost totally unproductive of any prudential rules by which he shall be enabled to avoid the calamities of the world, or any valuable remedy by which he can overcome them. To the politician, indeed, the study of history holds out some indipensable advantages. It is there he can safely learn the fallaciousness of prosperous appearances, the vanity of narrow expedients and temporising compliances, the hazard of despising, neglecting, and thwarting popular prejudices, and the certainty of mischief as the consequence of goading the passions beyond the well ascertained limits of practicable endurance. He may perceive by it the imperious necessity and the benefits of husbanding the national resources, and securing popular opinion, against a time when both shall be required in defence of the vital interests of the state; it may furnish him with the habit of discriminating between the imperishable laws of society, and the accidental and trivial institutions by which communities are often for a short time united; it may yield him, in short, or, more properly speaking, it may aid and foster the capability of managing public affairs, by furnishing precedents and inductive conclusions; though, after all, it be questionable, whether the process be likely to augment respect for his species, or to render him more indulgent and sympathising to its weaknesses and misfortunes.

The labours of the professed biographer, and even the occasional portraits which the historian is so often induced to delineate, are more level to ordinary conceptions and interests, and may be more easily appreciated by personal observation. The life of an individual, however exalted above our own station, and however different the circumstances in which he was placed, is nevertheless in many respects a transcript of one's self. He had the insignificance and the fretfulness of infancy, and the waywardness and impatience of youth,—he projected schemes of felicity, and was disappointed,—he trusted appearances, and was deceived,—resolved to be wiser in future, but surrendered his invincible judgment to the next gay vision which flitted across his fancy,—the necessity for exertion, either to procure a livelihood, or to gratify his ambition, was accompanied by feverish anxiety, and followed by desponding indolence,—perhaps he gave 'hostages to fortune,' married and had children, so multiplied the points on which his little comfort might be assailed, for the uncertain chance of an additional share of happiness,—he had his embarrassments and gloomy days, or if sunshine beamed on his toils and flattered his hopes, it gendered also the caterpillar and viper that envied and marred his prosperity,—the cup of joy which he had been anxiously endeavouring to fill, by years of self-denial and industry, never reaches his lips, or falls from them at the very moment of tasting,—pain, and sickness, and languor, render him burdensome to himself, and are but preludes to that closing event, which is only one of the many affecting scenes in which it shall certainly be our lot to resemble him. Such may be the general causes of that high interest which most persons take in biography. There are many additional reasons for it, though of rather more partial application. Some of these point out the sort of utility of which it may be instrumental.

The person whose life is recorded must have been somewhat remarkable for talents, for actions, for character, attainments, or fortunes. Millions of mankind pass through the world without attracting a single eye beyond the narrow circle of their families. They breathe, and sigh, and struggle, rejoice and lament, in their primitive obscurity, unheeded and unknown, quietly and usefully it may be, filling up the vacuities of society, and ministering to the common wants of their fellow creatures. These are not the proper subjects for biography. Even the zeal of ardent friendship, and the affection of kindred, have rarely brought forward an individual to the public gaze who had not been previously signalized by endowment, or qualification, or conduct. It is only the eminent poet, the painter or musician, the philosopher, the soldier, or statesman, the man of genius who has created a world around him, or whose productions and deeds have blazoned the time and place in which he lived, that can justify the distinctions of literature, or furnish materials for its labour. Of such persons, it is equally important and curious to know much more than can ordinarily be learned from their works. A man of this kind is less a private individual than 'a child of the state,' and is necessarily exposed to public scrutiny, and even the inquiries of posterity, to whom he answers the purpose of a land-mark, and evidence of a former world.

Great reputations are rare—the excellence which can compel them is still rarer. How have they been obtained? What was the concurrence of circumstances, or whence the power whose agency has perpetuated the names of illustrious men beyond the vulgar notoriety of their age and country? In what manner was that hand trained which so exquisitely spread existence, and intelligence, and feeling, on the unmeaning canvass? Where was the eye enriched, beyond the ordinary blessings of vision, whence emanated those interesting groups which people the landscape,—yon peaceful hamlet, with its during bowers, and greensward enclosure, and busied animation,—yon sloped and softened bank, where the mouldered turret projects its rugged shadow on the sunbeam's glare, defying the farther ravages of time,—yon azure expanse, so gently fringed with woolly clouds, and indented with the beech tree's straggling branches? What elementary harmonies suggested to Handel the ideas of his seraphic commentaries? What calamities urged, and were soothed by the thrilling melodies of a Mozart? What amplitude of soul broke forth in the symphonies of a Haydn? Did the fervour of Milton's muse diffuse warmth through his youthful poetry, or suddenly irradiate the effusions of his riper genius? In what magic creation was the spirit of Shakespeare so naturalised that he culled at will the choicest flowers of fancy, and breathed, as his proper element, the atmosphere of inspiration? How and where reposed the eloquence of Cicero or Burke, till the necessities of the state, or the hardihood of villainy, bade their thunder roar, and shake the strongest battlements of corruption? What supported the magnanimity of a Chatham against royal prejudices, and the clamours of popular enthusiasm? Were there any peculiarities in the modesty of his temper, or the occupations of his retirement, which carried Newton above the philosophy of his cotemporaries, and brought him into acquaintce with the presiding powers of the universe? These are some of the many questions which every intelligent mind naturally demands in the view of whatever is excellent or praise-worthy of its kind, and to which it is the duty of the biographer to afford suitable replies. He professes to connect together the insulated events and works which have obtained publicity and fame,—to assign the real internal causes of their celebrity—to fill up the chasm between non-entity and the productions or qualities which have sanctioned admiration or drawn forth gratitude,—in a word, to renovate and render permanently accessible a worthiness which has ceased to exist. This task is evidently a trying one, and requires for its accomplishment a peculiar assemblage of properties and materials, which comparatively few who have undertaken it appear to have enjoyed.

The causes of the deficiency, generally speaking, are more to be deplored than condemned, and may therefore be glanced at without invidious disparagement. They may be arranged under three heads:—1. Imperfection or inadequacy of information;—2.

Biography

Unsuitableness, or want of talent;—3. Disqualifying temper of mind, or personal bias.

The first of these causes is perhaps the most prolific of failure. This is easily explained. The biographer cannot be expected to have more copious materials than the individual whom he means to pourtray. But how few persons are there who have had that amount, and kind of foresight, to say nothing of the industry and intelligence requisite to give it efficiency, which could prompt to the preservation of adequate memorials of their studies, their experiences, and projects? What memory can retrace the first suggestions of genius, which, animating and buoyant, and productive as they might be, were speedily dissipated in the engagements of life, or indistinguishably incorporated with their own successive offspring? What space could be reasonably spared, or at least is ordinarily given to reflection, from the aspiring capabilities of youth, its devotion to novelty, its splendid purposes, and exorbitant anticipations? It is even questionable if the every-day-memorandum disposition, were it a practicable endowment, be consistent with the luxuriance and freedom, and facility of mind, from which excellence has its impulse. Certain at least it is, that an over solicitude for punctuality and method is injurious to mental power, and betokens any thing rather than the enthusiasm of genius. Some casual recollections of his pursuits, accordingly,—a treasured feeling of affection towards a favourite author,—a conscious propensity to intermit duty and abandon interest when certain ideas shoot across his mind,—perhaps an ill-judged fondness for some relic of his youthful toil,—or the prevalence of an ungainly habit over the dictates of understanding and the claims of politeness,—are the only beacons which cast a gleam on the darkened regions of his past existence. But even these are for the most part retained in secret, as if too valuable to be exposed to the regard of mankind, and are not unusually extinguished for ever in the dissolution of the individual possessor. What hope that the sagacity of any other person shall penetrate the obscure, or collect the scanty embers by which alone it can be explored! Even the most intimate relatives are often miserably ill-informed as to the interesting and really important features and transactions of their eminent associate. They are satisfied with his present fame, and delight in the kindness and complacency, and familiarity and ease, with which he shares his advantages and success among them, and feel no solicitude about the means by which the one was realised, or practically entertain any apprehension, till it be too late, of the period when the other shall be for ever withdrawn from them. Distance of time, and remoteness of situation, are other difficulties, under this head, which impede the performance of biography. How little is now known of the private manners, and even the public transactions of the ancient world? It is a chaos, amid the disorder and darkness of whose immensity, it is scarcely possible to obtain satisfactory information of any one character by which it had been either benefited or abused.

When unsuitableness, or want of talent, is mentioned as a source of imperfection, it is not meant to be implied that any peculiarity of faculty is requisite for the office of biographer. The allusion is made to unfavourable habits, to natural debility, or positive want of the common intellectual powers and moral sentiments. It is undeniable that scarcely any man, however great his intelligence, or vigorous his industry, is equally fit for every undertaking. The very peculiarities of his constitution and temperament by which he is discriminated from the rest of his species, lead him with greater facility and hope of excellence to one pursuit rather than to another; and it is equally certain, that the habits which his propensities may have occasioned, operate as a kind of restriction on his mental powers. There are numerous examples to illustrate this position, to which it is perfectly sufficient barely to advert, without entering on general reasoning, or the discussion of metaphysical principles. The mere mathematician would engage with little chance of success in the life of Otway, or Cowper, or Burns. He who had spent the bulk of his time in conning over lexicons, and scanning the measures of the ancient tragedians, would make but a sorry figure as the delineator of Raphael, of Reynolds, or of Barry. The character of Galileo, or Newton, or D'Alembert, would receive but little elucidation at the hands of a humourist like Foote, or even from the erudition and critical sagacity of a Toup or a Porson. It is needless to enumerate instances,—every one must perceive that the biographer ought to possess something in common with his subject; to have some resemblance in taste, and habitudes, and understanding, to be familiar with the studies in which his original was occupied, and to have trodden with some celerity, and for some time, the path which conducted him to reputation. The seeming exception to this law, in the case where merely moral character is to be displayed, requires but a moment's consideration to be disposed of. A corresponding equivalent is demanded on such an occasion, which perhaps is of still less frequent occurrence than due acquaintance with any one art or science,—a knowledge of human nature, and quick discernment of the invisible motives, and apparently inert objects by which it is actuated. Scantiness of this knowledge, or, which comes to the same thing, the substitution of hypothesis and system in its place, accounts for the worse vice than inutility of many compositions in this department of literature.

To the third head may be referred the whole host of attachments, prejudices, antipathies, and delusions, whether political, religious, literary, or personal. To any one of these idols strongly inherent in the mind, it is a thousand chances to one that truth will be sacrificed, and that too, perhaps, without the slightest consciousness on the part of the worshipper. A writer, under such possession, may furnish facts, it is allowed, though these will probably be garbled, partial, and incomplete, but is as utterly incapacitated for furnishing a *life*, as the mould which is constructed for an Apollo, a Trajan, or an Antonine, to yield the bust of Vulcan, Caligula, or Domitian. Even the sturdy morality of a Johnson contends unhappily at times with his prepossessions, and in one instance at least, proved insufficient to guard his reputation for honesty against a very painful and humiliating aspersion.

Various methods have been adopted in the execution of biography, each of which has its advantages and inconveniencies. The simple narrative style, proceeding in chronological order, has been preferred by many writers for the sake of its correspondence with the continuous course of real life. It is entitled to the commendation of apparent exactness, but is apt to be defective in proper *keeping*, to use the language of painters, by giving disproportioned space and colouring to events, from the circumstance of the length of time which they occupied, and allows comparatively little importance to those momentary glances of intellect, and sudden transitions of sentiment, by which, however, though without being immediately productive of external indications, the whole character is remodelled. This plan, moreover, seems to imply the absence of design and appropriate discrimination, and is in consequence rather discreditable to the author, even admitting his success as to the main object he has in view. A modification of this method separates the life into various portions designated by some striking event, and treats of each in natural succession from the birth to the decease of the individual.

Other biographers have seized on some of the prominent features, or what may be denominated the exterior parts of their constituents, on which they bestow the chief labour of their composition, leaving the subsidiary and merely personal circumstances to serve as a sort of appendix to the performance. There are not wanting examples, even of an exclusively technical biography, if the phrase be allowable, which direct the attention altogether to the public relations and bearings of the character. This seems proper enough as an auxiliary to history, but is necessarily confined to the few personages whose lives have borne decisive influence on their age and country. The chief objection to this plan is its tendency to disjoin the individual from his actions and productions, or to create a sort of intermediate being, in whose anomalous existence, as it is almost impossible to believe, it is equally so to be interested. It would be utterly intolerable if correctly adhered to; but the absurdity of writing merely the medical history of a physician, the political life of a statesman, or the literary memoirs of a scholar, is too glaring a violation of common sense to be frequently committed by any who are at all competent to the demands of biography.

The superior chance of verisimilitude and authenticity which a man's writing his own life appears to possess over the reports and conjectures of any other person, has suggested the idea of occasionally introducing him as a narrator, by publishing his letters, or extracts from them, as obtained from his correspondents. Of the value of this substitute it is impossible to doubt. Yet there adheres to the practice, unless very guardedly and tenderly displayed, an appearance of unfairness and irreverent exposure towards the departed individual, which cannot fail to excite painful emotions in the delicate or susceptible reader. A presumption, besides, is very apt to arise in his mind, not to the advantage of the biographer's industry and skill. It would be better in general, it is apprehended, to insert the letters in the appendix as an authority, on the supposition that it is *just* and expedient to publish them at all, and to employ their contents, like any other materials, in the construction of the memoir.

The mode, it is reasonable to imagine, ought to be varied according to the nature of the case and the object intended. Perhaps the philosophical idea of the purpose of biography will generally lead to the precise means of accomplishing it. It is the representation of an individual, in the totality of his character, as contemplated in the gradations, incidents, and operations of his being, in conjunction with the physical and moral peculiarities of his constitution, and as arrayed in the natural or superinduced garb, manner, and behaviour which discriminated him from the rest of mankind while living.

A late publication by Mr Stanfield, on the subject of biography considered as a literary art, professes to specify its numerous difficulties and the means by which they are to be encountered and overcome.

BIRCH, Thomas, a voluminous English writer, descended from a family of quakers, was born in London in 1705, and, more inclined to literary pursuits than the mechanical employment in which his father was engaged, and to which he was destined, he devoted his labours to study and the acquisition of knowledge; officiated as usher in several public seminaries; and, without the advantage of a university education, was admitted to orders in the church of England. He obtained various preferments, and was elected one of the secretaries of the Royal Society, of the origin and progress of which he published a history, in four volumes 4to. Dr Birch was unfortunately killed by a fall from his horse in 1766, and in the 61st year of his age. With the assistance of several associates, he completed the elaborate undertaking of *The General Dictionary, Historical and Critical*, in 10 volumes, folio; and he published editions of various works of some of the older English writers, with biographical sketches, and different memoirs and historical tracts.

BIRD, for an account of the structure, see Anatomy; and for the classification and natural history, see Ornithology.

BIRD ISLAND, a huge rock in the southern Pacific ocean, three miles in circuit, and rising to a great height; precipitous on all sides, excepting to the westward, where it declines into a sandy beach, and exhibiting some marks of vegetation. As the name indicates, it is the abode of immense flocks of birds, and is more than 100 miles distant from the Sandwich islands.

BIRMAH, or BIRMAN EMPIRE. The countries of Ava, Arracan, and Pegu, recently independent kingdoms in the eastern peninsula of India, are now united under the sway of one sovereign, and distinguished by the name of the Birman Empire. The territories of this formidable power are situated between the 9° and the 26° of north latitude, and the 92° and 107° of longitude east from Greenwich, spreading over a surface of 200,000 square miles.

Birmah.

The western boundary of this empire is washed to a great extent by the bay of Bengal; towards the north the river Nauf, and a range of mountains, separate it on the same side from the possessions of the British East India Company. In no other direction have its limits been hitherto accurately ascertained; it is only known generally to reach to Assam and Tibet on the north, to China and Laos on the east, and to Siam and Malacca on the south. But the frontiers of a country, inhabited by people of a warlike disposition, encircled by neighbours equally prone to hostilities, must of course accompany the progress of conquest, whether it advances or recedes.

General aspect.—The external character of this extensive country, is, as we have reason to expect, greatly diversified, both in point of soil and surface. Its sea coast, which stretches upwards of fifteen geographical degrees in length, is fringed throughout by numerous islands, is indented at frequent intervals by jutting capes and retiring creeks, and is broken at various places by the mouths of many a stream; here it spreads out into a flat and sandy beach, exposed to the alternate influence of the flowing tide and the scorching sun; there it rises, with a precipitous abruptness, into proud and craggy cliffs, which sullenly repel the rage of the boisterous billows. Independent chains of lofty mountains, and branches of the stupendous ranges of Tibet, clothed with forests, or green with pastures, traverse the country. From these mountains innumerable torrents roll their streams, mingle together in the vallies, and having swollen into magnificent rivers, wind their way to the ocean through boundless plains, teeming with the richest variety of tropical vegetation. "From a temple, (says Captain Symes,) that stands on a commanding cliff close to the river Irrawaddy, the eye is gratified by a delightful combination of natural beauties: a fine sheet of water three miles in breadth, broken by an island about a mile long and half a mile wide, covered with trees of luxuriant foliage; eminences from the opposite shore, that rise from gently swelling grounds, clothed with wood, to brown and rugged mountains, which, receding in an oblique direction, leave to the view a level plain." And this, though the description of a particular landscape, is characteristic of many others equally beautiful and picturesque.

Mountains and rivers.—Many mountainous ridges from the towering heights of Tibet extend across the northern provinces of the Birman empire, and give it on that side the character of a hilly country. An extensive independent chain, called the great western mountains, runs along the coast, penetrates in a direction bending toward Bengal, far into the interior, and forms the boundary between the countries of Arracan and Ava. Another independent chain, denominated the Galladzet hills, traverses the territory of the ancient kingdom of Pegu, about one hundred miles above the city of that name. The principal rivers of this region are the Irrawaddy, the Setang, the Thalanyn, the Maygue, and the Maykaung, concerning which, and some of the less considerable streams, Dr Buchanan, who accompanied the embassy to the court of Ava in 1795, has communicated the following important information: It appears, (he observes as the result of his inquiries,) that the Arracan river is not so considerable as what has been supposed, but takes its rise in hills at no great distance to the north: That the river coming from Tibet, which is supposed to be that of Arracan, is, in fact, the Keenduem, the great western branch of the Ava river: That what is supposed to be the western branch of the Irrawaddy, is, in fact, the eastern one which passes by Ava, and runs to the north, keeping west from the province of Yunan, and leaving between it and that part of China a country subject to the Birmans: That the Lokiang, which is supposed to be the great branch of the Irrawaddy, has no communication with that river; but on entering the Birman dominions assumes the name of the Thuluang, and falls into the sea at Martaban: That the river Pegu, which is supposed to come from China, rises among the hills about a hundred miles from the sea, and which forms the boundary between the Birman and the Pegu kingdoms: That between the Pegu and Martaban rivers there is a lake from which two rivers proceed, the one runs north to Old Ava, where it joins Myoungnya, or Little River of Ava, which comes from mountains on the frontiers of China; the other river runs south from the lake to the sea, and is the Setang river in the map: That the rivers of China, which are supposed to be the heads of the Pegu river, are those of the Siam: That the rivers of Siam and Cambodia communicate by a very considerable branch called the Annan. These rivers, on entering the level land, formed chiefly by their depositions, cross and divide it in every direction by the branches into which they are separated, and fall at last by many mouths into the waters of the ocean.

Climate.—A country situated chiefly between the tropics must necessarily experience a high degree of temperature; but the health and vigour and longevity of the inhabitants afford an incontestible proof of its salubrity. The seasons are regular, and it is not subject to the extremes of heat and cold; for the intense heat which precedes the rainy season is of too short continuance to cause much inconvenience. Here, as in other tropical countries, the year is divided into the dry and rainy monsoons.

Productions.—In the richness and variety of its mineral productions the Birman empire is unrivalled. Mines of gold and silver are open in several places, and ores of iron, tin, lead, and arsenic are found in great abundance; rubies, sapphires, amethysts, garnets, chrysolites, jaspers, and other precious stones, all of the finest water, also abound in it; there are quarries of excellent marble in many of its mountains, and no other country yields amber, antimony, sulphur, or petroleum in larger quantity, or of finer quality. The soil of the southern provinces of this region is remarkably fertile, and yields as luxuriant crops of rice as are produced in the finest parts of Bengal; wheat and other grain, with a great variety of esculent herbs, grow to perfection, and in great profusion, in the vallies of its more northern and higher districts; sugar-canes, tobacco, indigo, brown and white cotton, and all the variety of tropical fruits, are among the indigenous productions of this highly favoured land; its mountain declivities also are clothed with immense forests, in which the teak abounds, a tree almost peculiar to this country, possessing qua-

Birmah.

lities suited for ship-building superior even to the oak, and therefore, in relation to her East India possessions, of incalculable importance to Great Britain.

The same animals prevail here as in hither India, such as the elephant, the horse, the antelope, the deer, the bull, the buffaloe, the tyger, &c. ducks in great variety, jungle-fowl, peacocks, storks, &c. also serpents and lizards, with other reptiles, in greater abundance than is always pleasant or safe.

Inhabitants.—Dr Buchanan is of opinion that the Birmans are a Tartar tribe. He tells us, that, like those of this race, they are distinguished by a short, squat, robust, fleshy stature; that their face assumes the shape of a lozenge, being broad at the cheekbones, and narrow at the forehead and chin; that their hair is harsh, lank, and black; and that their complexion neither darkens into the deep black of the Hindoo, nor beams out in the clear bloom of the European. The lower orders observe the savage custom of tattooing their arms and thighs, with the view of charming off the weapons of their enemies. A more peculiar custom is practised by their women: Girls at an early age are taught to turn the joint of the elbow round to the side, a circumstance which gives to their arms a distorted appearance. Their articulation seems to a stranger extremely indistinct, which may be occasioned by their excessive use of betel, &c. No man of rank speaks without his mouth being full of betel, tobacco, quicklime, and spices; hence indistinct articulation has become fashionable. With the variety of dialect, the same language is spoken throughout the empire, and also in some of the neighbouring states.

Population.—Few of the Birmans live in solitary habitations, but in cities, towns, and villages, of which the kingdoms of Ava and Pegu are said to contain 8000; and allowing to each of these, on an average, 300 houses, and to every house six inhabitants, the aggregate of the whole will be 14,400,000; and estimating the kingdom of Arracan in a similar manner, the number will increase to between seventeen and 20,000,000. This, indeed, is an uncertain method of calculation; it is, however, the only attempt that has hitherto been made to ascertain the population of this interesting part of the world.

Cities.—The habitations of this people are universally raised from the ground on posts of bamboo, or pillars of strong timber, in proportion to their weight and size. The areas of their cities are of a quadrangular form, fortified by a wall and a ditch; the streets are straight and spacious; they frequently intersect at right angles, and many of them are paved with brick. They are adorned with magnificent temples, profusely gilt; and even the private houses, though constructed chiefly of wood, have a splendid appearance. Ummerapoora, the capital of the empire, though founded so late as the year 1785, has already become one of the most flourishing cities of Asia. It stands more than 400 miles up the Irrawaddy, washed on the west by that river, and on the east by the waters of a lake. The fort is an exact square, within which are magazines of grain, military stores, &c. The royal palace occupies the centre, adjacent to which is the hall of council, supported on eleven rows of pillars. At each corner stands a temple, richly gilded, and a hundred feet in height; and many others far more magnificent are dispersed through the city. Four miles down the river are the ruins of Ava, the former metropolis. Its walls, once deemed invulnerable, now mantled with ivy, and mouldering into heaps; its temples, recently so splendid and so perfect, now the dwelling-place of noisome bats, and swiftly dilapidating under the impressions of the hand of time; and its streets, lately so crowded with busy multitudes, now covered with rank jungle grass and the fast growing bamboo, are fitted to inspire a melancholy sentiment, and to suggest the transient nature of all human grandeur. Chagaing, fronting the capital on the opposite bank of the river, was once the royal residence, and is still a populous and a mercantile city. Pegu also, once the metropolis of the kingdom of that name, was taken and sacked in 1757, and left in ruins. A new town, however, has been built within the area of the old, and it may soon regain its former magnificence. Arracan is the capital of the country which bears that name. Rangoon, situated on the eastmost branch of the river Irrawaddy, is a great sea-port, with an excellent harbour. It has long been an asylum for insolvent debtors. Prome is renowned in Birman history for having been the scene of many long sieges. Martaban and Mergni stand on the bay of Bengal, and possess excellent harbours. Besides these, there are many other cities, towns, and villages, built chiefly on the banks of the rivers. The wooden fabrics of which these cities, &c. are composed, make them extremely obnoxious to fire; and several precautions are taken against its effects by the inhabitants. Pots filled with water are ranged along the roofs; each house is provided with two bamboo poles, one with a hook attached to it to pull down the thatch, another furnished with an iron grating to suppress the flames by pressure.

Agriculture.—This country is too highly favoured by nature, and the wants of the people are too easily satisfied, for the art of agriculture to be skilfully practised; and till it was united under the auspices of one sovereign, it was too frequently exposed to the ravages of internal war to afford encouragement to the labours of the husbandman. The capacity of the soil, however, is extremely great, and might easily be made to yield more than a hundred fold. The plough here is a very rude and imperfect implement, and is drawn by oxen, as are also their carts. The fields in some places are inclosed with hedges, and the rice plantations are surrounded with embankments.

Manufactures.—The Birmans do not yet manufacture for a foreign market, but they work up a great many articles for their own use. The architecture and gilding of their temples imply skilful and dexterous artificers. They also excel in ship-building. Of their fine marble they form innumerable statues of their god Gaudma. They manufacture fabrics of silk and cotton not inferior to those of Bengal. Common salt, saltpetre, and gunpowder, are made by them in great quantities. They make great variety of lackered and earthen ware. In 1795, the monarch was anxious to avail himself of the presence of the gentlemen of the English deputation to improve his people in glass-making; but none of themselves having ever been initiated, they were unable to reveal the mysteries of the glass-house; they, however, furnished his majesty's subjects with all the information the Encyclopædia Britannica contained on the subject. This anecdote shews that this people are not above instruction, and therefore open to improvement.

Ranks.—The odious and degrading distinction of cast is entirely unknown in this country; nor are the women immured within the walls of a haram, or guarded by eunuchs, as in most other eastern nations; they have here, indeed, as much liberty as in Europe. The privileges of the nobility, however, are very scrupulously protected. The badge of the order is a chain composed of several strings, from two to twelve, according to the rank of the wearer. The king alone is decorated with a chain of twenty-four strings. But the order of nobility is distinguished by every thing belonging to them. From the houses in which they dwell, to the box which holds their betel, marks of their rank, which it is felony for a plebeian to assume, are conspicuously displayed.

Government.—Elevation of rank, however, affords to the possessor no title to engross, or even to share the offices of the state. The government of this empire recognises no hereditary dignities or employments. They all proceed from, and revert to the sovereign, who, though he administers the affairs of the empire through the medium of a numerous council, may be regarded as in full possession of absolute power. The court is splendid and ceremonious. The king is invisible, except on great occasions of state. The provinces are governed by a deputy, called Maywoon, an office which is sometimes held by the princes of the blood.

Revenue.—The sacred law allows the tenth part of the produce for the use of the state. A tenth on most imported goods is taken in kind, and distributed to the dependants of the court in place of salaries. The princes of the blood receive grants of provinces, cities, &c. to support their dignity. The Birman government exhibits almost a faithful picture of Europe during the dark ages, when the principles of feudal dependence were established by the barbarians of the north.

Army.—The regular army of this power is not large, but every man in the empire is liable to be called upon for his military service; and war is deemed an honourable occupation. When an army is to be raised, a mandate is issued from the golden palace to all the viceroys of provinces, requiring a certain number of men to assemble at a general rendezvous on an appointed day. The levy is supplied with arms, ammunition, and a certain daily allowance of grain, but is entitled to no pay. The friends at home are accountable for the good behaviour and fidelity of their relatives in arms,—a barbarous custom, sometimes productive of the greatest cruelty. The infantry wear no uniform, which gives them a grotesque and mobbish appearance. The cavalry are all natives of Cassay, and are accounted excellent horsemen. But war-boats constitute the most formidable part of the Birman military force. Every town of any magnitude is obliged to furnish these, with their entire equipment, in proportion to its size and resources. At a very short notice, the king can command more than five hundred of these vessels.

Religion.—The Birmans are votaries of Buddha, or, according to the more common appellation, of Gaudma, who is allowed by the Hindoos to be the ninth Avatar, or incarnation of the Deity in the capacity of preserver. Sublime and holy attributes are thought to characterise this personage, which, however, comport extremely ill with his representations, which are rude statues of the human form, larger than the life, generally of marble, placed cross-legged upon a pedestal, with one arm pendant, and the other brought across the body. These images are very common throughout the country, and are objects of the most profound veneration. Numerous and magnificent temples are reared at a vast expence in all the cities, and in many other places, for the worship of their divinity. They are commonly built in a pyramidical form; and many of them rise to the height of five hundred feet. The most stupendous of these piles is the temple at Pegu, denominated *Shoemadoo*, or *Golden Supreme*. This extraordinary structure is erected on a double terrace, one raised above another, ascended by flights of stone steps; on every side are the dwellings of the priests, raised on timbers five or six feet from the ground. The temple is built solid of brick, without any aperture; it is octagonal at the base, and spiral at the top; each side of the base measures a hundred and sixty-two feet; a breadth which quickly diminishes as it ascends. The spire is surmounted by the *tee*, or umbrella of open iron work; from which rises a rod, with a gilded pennon. The priests of Gaudma are called Rahaans, and resemble monks in their mode of life. Celibacy is strictly enjoined; they live in convents, wear a yellow garment, and go barefooted; their manners are simple, and their lives decent; they receive contributions of food from the laity. For this purpose they perambulate the streets with a quick pace, carrying a basket, and take what is voluntarily offered to them. They profess to spend the chief part of their time in the contemplation of the divine essence. There were once many nunneries in the country, but they have been suppressed as unfriendly to population. A most favourable feature of the Birman religion is the universal toleration which it allows. This people never trouble themselves with the religious opinions of those who visit or who dwell among them, provided they disturb not them in the exercise of their worship. Mahometans, Jews, and Christians, are summoned to prayers, in their respective manners, often in the same street. Processions meet and pass, without giving or taking the smallest offence. Persons who sustain the character of preachers of religion, no matter what be the species or the sect, enjoy greater privileges, by the order of government, than those who act in any other capacity.

Laws.—The Birman laws are closely interwoven with their religion. They are deemed of divine authority, promulgated by *Menu* from inspiration. And it must be confessed that the code is replete with good sense and sound morality. It provides specifically for almost every species of crime that can be committed; and adds a copious chapter of precedents and decisions to guide the inexperienced in cases of doubt and difficulty. It tells the prince and the magistrate their duty in language, austere, manly, and energetic. But the chapter on women is offensively indecent, and it sanctions the absurdity of trial by ordeal.

Literature.—The accomplishments of reading and writing are very generally diffused among this people. They are common even among the peasantry. They write from left to right, like Europeans, and their character is very elegant. In the king's library are books in history, medicine, law, and poetry. These books are kept in chests, curiously ornamented with gilding and japan, in which the volumes are arranged under distinct heads.

Customs and character.—With regard to their food, though their religion forbids the taking away of animal life, it does not prohibit the eating of flesh; and therefore game of all kinds is regularly sought and sold in the markets: For they interpret the prohibition of religion to apply merely to domesticated animals. Rice, fruit, and vegetables, constitute their principal aliment; though even serpents and lizards are not rejected by the lower orders. Their dress varies according to their rank. The lowest class of females wear sometimes only a single garment, in the form of a sheet, which, wrapped round the body, and tucked in under the arm, crosses their breasts, which it scarcely conceals, and descends to their ancles; thus, when they walk, the bottom of the cloth, where it overlaps, is necessarily opened by the protrusion of the leg, and displays a side view as high as the middle of the thigh. But a more decent dress is in general use. A short shift, drawn tight by strings, supports the breasts, over which is worn a loose jacket, with long sleeves. Round their waist they roll a long piece of silk or cloth, which reaching to their feet, and sometimes trailing on the ground, encircles them twice, and is then tucked in. The men wear large ear-rings of various forms; frequently they are tubes of gold, about the thickness of a quill at the one end, and expanded at the other like the mouth of a speaking trumpet. The court dress is very becoming; it consists of a long robe, either of satin or velvet, reaching to the ancles, with an open collar and loose sleeves; over this there is a scarf or flowing mantle. On their heads they wear embroidered caps, ornamented according to the rank of the wearers. The law prohibits polygamy; but a man may keep as many concubines as he pleases or can maintain. They burn or embalm their dead, which is always a religious service. Begging is unknown in this country. Their mode of welcoming in the year is singular: In order to wash away all past impurities, women have the privilege of throwing water on every man they meet; and receive a wetting in their turn with perfect good humour. On the last day of the year the young women arm themselves with flaggons and long syringes, and prepare to give the men a wet reception; yet notwithstanding this licence, no indecency is committed, nor do evil consequences ensue. In this singular amusement the men are never the aggressors. Chess is a favourite game among the Birmans, and many of them are skilful players. They are fond of fire-works, boxing matches, puppet shews, theatrical entertainments, singing and dancing.

It is obvious from the whole of these details, that this nation has made considerable advances in civilization, perhaps as great as our own ancestors a very few centuries ago. As may be expected in such a state, the character which these people display is of a mixed and even a seemingly inconsistent kind. They are humane or cruel, indolent or active, refined or gross, faithful, treacherous, sullen or cheerful, according as their unformed manners, and ill regulated minds happen to be under the influence of the spirit of the civilized or the savage state. There seems however to exist no insurmountable barrier in the way of their improvement, like that which opposes the progress of their Hindoo neighbours; and we are thereby led to believe with Captain Symes, that they are destined to rise rapidly in the scale of civilization. With respect to the importance of the Birman empire, in a commercial point of view, there can be no dispute. It possesses the advantage of water-carriage, not only from the great extent of coast, but by means of its navigable rivers opening communications with the principal parts of the country. Its climate is most salubrious; its productions are various, as they are valuable; its situation is commodious for intercourse with India, with China, with the South-sea islands, and even with Europe. Its people are fond of our manufactured commodities, and the recent abridgement of monopoly encourages a free trade with all the rich regions of the east.

History.—In the time of the earliest of our European concerns with this part of India, the Birman sovereign held the kingdom of Pegu in a kind of subjection, and exacted a tribute from its prince. In 1744, the Peguvians, imagining that they had power to throw off the yoke of the Birmans, not only renounced their obedience, but having tried their strength they pushed their enterprize still farther. They entered the Birman territory, and in 1752 took possession of Ava its capital, made its monarch a captive, and totally reduced the kingdom. An instrument, apparently feeble, was the author of the next revolution, the period of which was not long delayed. Alompra, a Birman of low extraction, the head of a petty village, was provoked to oppose the insolence of his Peguvian masters, and to drive them from his village. He was quickly joined by a band of supporters; they enabled him to defeat a small body of the enemy sent to chastise him. The ardour of the Birman was roused, and the man, notwithstanding the meanness of his birth and education, had talents to improve his advantages. He became the leader of his countrymen against their invaders. Towards the conclusion of the year 1753 he obtained possession of Ava the capital, and gained a victory over the king of Pegu, who marched in person to oppose him. Having now cleared of its enemies the greater part of his native country, he was recognized as the founder of a new dynasty, and had no inclination to stop in his victorious career. He not only recovered from the Peguvians whatever part of the Birman dominions they had usurped, but proceeded to attack them in their own territories. They were by no means able to withstand his arms; and, in 1757, Birmingham

he had so far pushed his conquests as to be able to invest their capital, which, after a short resistance, submitted, and the kingdom was delivered into his hands. He was now one of the most powerful sovereigns of the east. While he led his army against the Siamese he was seized with a distemper which quickly put a period to his life and the war in which he was engaged, in the year 1760. His son reigned in his stead; and on his demise, in 1764, his brother Shemuan, to the prejudice of his infant nephew, succeeded to the throne. He repelled a Chinese invasion, the government of which had become jealous of the Birman power. In 1783, he conquered the kingdom of Arracan, and united it to the empire. About the year 1793, some of the Birman troops made an incursion into the British possessions, in search of some robbers who had taken refuge there. A negotiation took place; the robbers were found guilty, and delivered up to their countrymen. This accidental event led to the embassy which has brought us acquainted with this interesting country. See Symes's *Account of the Embassy to Ava*.

BIRMINGHAM, a town of Warwickshire in England, which is celebrated for its numerous and extensive manufactures of hard ware goods, is finely situated on a declivity, is about two miles long, and somewhat of a crescent form. The climate of Birmingham, although the air is continually loaded with smoke and noxious vapours, from a crowded population and so many manufactures, is remarkable for its salubrity.

The lower part of the town is chiefly inhabited by manufacturers, and is occupied with their warehouses and workshops; but in the higher part the streets are regular and spacious, with many elegant buildings. The parish church of St Martin, which dates its origin in 1300, has a lofty spire; and St Philip's, or the new church, is an elegant edifice, adorned with a square tower and cupola, which is furnished with a peal of bells and a clock with musical chimes; and, beside these churches, the chapels and meeting-houses for different sects are numerous. Birmingham has the advantage of institutions for the education of the poor, for the support of the infirm, and for the relief of the diseased; public libraries, some of which are well furnished with books; a museum, in which are exhibited various objects of natural history; hot and cold baths on a large scale; a theatre, and a Vauxhall for music and other entertainments.

Birmingham is not incorporated; the municipal officers, composed of a high and low bailiff, two constables, and a head borough, are elected annually; and a court of requests, established by act of Parliament in 1752, meets every Friday for the dispatch of legal business.

Birmingham is justly regarded as one of the first manufacturing towns in the world. The tanning of leather was the chief occupation of the inhabitants in the earlier periods of its history; but after the commencement of the nineteenth century, this branch of trade declined, and is now nearly abandoned. Coarse iron wares were the only manufactures of that description before the revolution, at which time it had been usual to be supplied with fire-arms from abroad. The member of parliament from Warwickshire undertook to obtain a sufficient supply from Birmingham; the order was punctually executed; and it has since continued to furnish the largest proportion of muskets, swords, and other small arms. Various other branches of hardware manufactures were afterwards introduced; and whether they are useful, curious, or ornamental productions, they display in a remarkable manner the enterprise and ingenuity of the proprietors and managers, and the industry and delicacy of hand of the workmen and artizans. Of the progress and extent of the manufactures of Birmingham, a singular instance is recorded of Mr Taylor, who introduced gilt buttons, japanned and gilt snuff boxes, with various articles of manufacture in enamel, and who died in 1775, at the age of 64, after amassing a fortune of L.200,000. The weekly produce of Mr Taylor's manufacture of buttons amounted to L.800; and in painting snuff boxes, at one farthing each, a man could gain L.3, 10s. per week.

The population of Birmingham has increased rapidly with its thriving manufactures, since the commencement of the eighteenth century. The number of streets which at that time was not more than 30, now exceeds 250. The inhabitants, who, in 1801, were estimated at 73,670, of which number more than 62,000 were employed in trade and manufactures, had increased, in 1811, to 80,753.

Soho.—Soho, which, from the similarity of its manufactures, may be considered as connected with Birmingham, exhibits a remarkable example of enterprise, ingenuity, and industry. This remarkable spot, which is about two miles distant from Birmingham, and which, within the last 50 years, was a solitary waste, is now covered with plenty and population. The manufacture of metallic toys by the late Mr Boulton, in conjunction with his partner Mr Fothergill, was the commencement of these extensive works. Plated ware, or Sheffield plate, including various useful and ornamental articles, was next introduced. These were succeeded by a happy imitation of the French *or moulu* ornaments, composed of vases, tripods, and other works, and by elegant and massive services of silver plate. The establishment of a manufactory of steam engines, when Mr Watt, whose valuable improvements of that machine form a remarkable era in its history, became a partner in the concern, extended the celebrity as well as the profits of the works at Soho. In all the productions of this manufactory, whether in the form of large and powerful apparatus, or in that of trinkets and ornaments, novelty, taste, and ingenuity have been always conspicuous.

The coining apparatus, invented and constructed at Soho, is a singular example of mechanical ingenuity. The first coining mill was erected at this place in the year 1783, and after various improvements, eight machines, going at the same time, are driven by one steam engine. Each machine strikes from 70 to 80 pieces, of the size of a guinea, in a minute, so that between 30 and 40,000 coins are worked off by the whole eight machines in an hour. All the processes are conducted by machinery, as in copper coin,—rolling the masses of copper into sheets,—rolling them through cylindrical steel rollers,—clipping the pieces of copper for the dye,—shaking the coin in bags,—

striking both sides of the coin,—and then milling it. But one of the most curious contrivances of this ingenious machinery is, that a precise account of every piece coined is regularly kept, so that even the possibility of fraud is precluded.

Birmingham is 116 miles from London, and in its immediate vicinity two rich coal mines, and the extensive inland navigation by which the produce of its manufactures are conveyed to the principal towns of the interior of England, as well as to the chief sea-ports of the east and west coasts of the kingdom, for exportation, afford great facilities for enterprise and trade.

BISCAY, a province of Spain, bounded on the north by the bay of Biscay, on the east by Navarre, on the south and west by Old Castile and the Asturias. This province is about 40 miles in length, and about 24 in breadth, and is altogether a mountainous region, some parts of which rise to a considerable elevation. The valleys are devoted to agriculture; on some of the hills the hand of industry has succeeded in their cultivation to the very summit; and the higher districts afford pasture to herds of cattle. Fruits, particularly chesnuts, are abundant; the vine is extensively cultivated in some places, and the sides of the mountains are clothed with forest trees, or various shrubs of indigenous growth.

The mountains of Biscay afford abundance of excellent iron ore, and numerous works have been erected for the purpose of smelting the ore and manufacturing the iron. The rocks are limestone, sandstone, and various kinds of marble, and in some places argillaceous rocks predominate. Copper is enumerated among the minerals of Biscay; from salt springs common salt is obtained by boiling; and mineral waters, both hot and cold, are met with in several places.

The population of this province is estimated at 300,000, but it is said that it has decreased of late years. The chief towns are, Bilboa, with a population of 15,000, and some foreign trade; Vittoria, which numbers about 7000 inhabitants; and St Sebastians, a sea-port town, and strongly fortified, includes a population of 13,000. The abundance of iron affords materials for the manufacture of anchors, cannon, and other kinds of fire-arms, in different places; sheathing copper, and large boilers of the same metal, are fabricated at Toledo; and works for cordage and rigging are established in some of the other towns. It is said that the province of Biscay furnishes the best soldiers and sailors in Spain.

BISCUTELLA, Bastard Mithridate Mustard, a genus of plants belonging to the Tetradynamia class.

BISERRULA, Base Hatchet Vetch, a genus of plants belonging to the Diadelphia class.

BISERTA, a maritime town of the kingdom of Tunis in Africa, stands at the bottom of a fine gulf, and on the banks of a canal which forms a communication between the sea and a lake in the vicinity. The town is fortified, and defended by castles. The population, which was once more considerable, is estimated at 5000. The inhabitants are chiefly occupied in the fisheries on the lake, the millets of which are of a superior quality, and from their dried roes, botargo, which is exported to the Levant as a luxury, is made; and the surrounding territory produces corn, cotton, and various fruits.

BISHOP, a prelate who holds a barony of the king, and superintends the ecclesiastical government of his diocese. The word is derived from the Greek, signifying *inspector* or *overseer*. A similar denomination was given to certain officers among the Greeks and Romans. Of the origin of bishops, in the early ages of the Christian church, and of the nature of the authority with which they were invested, as the question involves the foundation of church government, no small diversity of opinion has prevailed. Those who are the advocates for the Episcopal establishment contend, that the name and authority of bishops were known in the earliest period of the church; and they consider the apostles themselves as bishops, from whom the jurisdiction of their successors is derived,—that the angels of the churches spoken of in the book of Revelation were the bishops of those churches,—and that some of the early fathers of the church actually received episcopal ordination from the apostles by imposition of hands. But, on the other hand, those who maintain the presbyterian form of church government, contend, that no superior jurisdiction was held either by the apostles or their immediate successors,—that the terms presbyter and bishop were applied to the same person,—and that the bishops or presbyters, in the time of the apostles, were the pastors of one congregation only; and indeed it is affirmed, that no examples are recorded of two or more churches being under the jurisdiction of one bishop. But, for a view of these arguments, reference may be made to Prettyman's *Elements of Christian Theology*, and Campbell's *Ecclesiastical History*.

The hierarchy of England is composed of two archbishops and twenty-four bishops, exclusive of the bishop of Sodor and Man, who has no seat in the House of Peers. The bishops of England are barons, and, as such, sit and vote in the House of Lords. A bishop has the title of *My Lord*, and is addressed *Right Reverend Father in God*. The bishops of London, Durham, and Winchester, take precedence of all the other bishops, who rank according to seniority of consecration. All bishops in the church of England are nominated by the king. When a vacancy happens, a *congé d' elire*, or permission to elect, is issued to the dean and chapter, with a recommendation of some person to the benefice, and the election must take place within twelve days. Consecration is then performed by the archbishop, or, in certain cases, by three bishops specially commissioned for that purpose.

BISHOPS AUCKLAND. See Auckland.

BISKUIT, or Biscuit, a kind of bread prepared in various ways. See Bread.

BISMILLAH, a solemn form of expression used by the Mahometans at the beginning of their writings and books, and signifying, *in the name of the most merciful God*.

BISMUTH, or tin glass, a metallic substance of a reddish or yellowish white colour. See Chemistry and Mineralogy.

BISSAGOS. See Bijuga.

BISSAO, an island on the north side of the Bijuga channel, on the west coast of Africa, about 40 miles long, and possessing a rich soil producing grain and fruits. The Portuguese had formerly a settlement on it for carrying on trade in wax, ivory, and slaves. The natives, like many of the African tribes, are greatly influenced by superstitious charms, of which some remarkable examples are recorded by Captain Beaver in his *African Memoranda.*

BISSUNPOOR, a district or zemindary in the province of Bengal, which includes about 1250 square miles, and is one of the most ancient estates in the province, for it appears that it has been in possession of the present proprietor's family for the long period of nearly 1100 years; and during this time they were almost independent, paying only a small tribute to the sovereign, until 1715, when the country was completely reduced. In this district the laws, the manners, and virtues of the Hindoos, are described as existing in the utmost purity and simplicity. But these accounts, it is probable, are not altogether divested of exaggeration.

BISSEXTILE, a term in chronology, denoting a year consisting of 366 days, and analogous to leap year.

BISTORT, the English name of the *Polygonum bistorta* of Linnæus, which at one time held a place in the list of medicines recommended by the colleges on account of its virtues as a tonic.

BITHYNIA, an ancient kingdom of Asia, having the Euxine sea on the north, and the Thracian Bosphorus on the west, was long governed by its own sovereigns, one of whom, Prusias II. gave an asylum to the celebrated Carthaginian general Hannibal, when he was driven from his own country, and at last betrayed him to the Romans; in the victorious career of that people, was subdued by their arms, and, on the decline of the eastern empire, fell under the dominion of the Turks, and still acknowledges the authority of the Ottoman Porte.

BIXA, ROUCOU, or ANOTTO TREE, a genus of plants belonging to the Polyandria class, and containing only one species, *orellana*, from the seeds of which the well-known dye-stuff is obtained. For the mode of preparation, see ANOTTO.

BLACK, DR JOSEPH, an eminent chemical philosopher, was born on the banks of the Garonne in France in the year 1728. His father, a native of Belfast in Ireland, but descended from a Scotch family, had resided long in France, and chiefly at Bourdeaux, as a merchant. The son, in his 12th year, was sent to Belfast for his education. From this place he removed to the university of Glasgow in 1746; and having directed his studies with a view to the medical profession, he was fortunate in becoming the pupil and friend of Dr Cullen, who lectured on chemistry; and with the aid of his powerful and penetrating genius, threw some rays on the feeble twilight which now preceded the bright day of the science which his young pupil was destined to illustrate and adorn. Mr Black removed to Edinburgh in 1750, where he completed his medical education. When he was admitted to the degree of doctor of medicine, he chose for the subject of his inaugural dissertation the investigation of the nature and properties of magnesia, in which he had been long engaged, and distinctly demonstrated the cause of causticity, or the difference between the earths and alkalies in their mild and caustic state.

When Dr Cullen was called to the university of Edinburgh, Dr Black was appointed professor of anatomy and lecturer on chemistry in 1756; but disliking the anatomical department of his labours he was permitted to exchange with the professor of medicine; and his lectures on the institutes of that science received a large share of his attention and study, while chemistry was only a secondary consideration. It seems indeed singular that the alluring path, which he had so successfully entered, was so soon abandoned. No record of his chemical researches, for several years after his appointment at Glasgow, is preserved; but, in 1761, he completed a series of experiments from which he deduced his doctrine of heat, which must ever be regarded as one of the most brilliant discoveries in the science, and one of the most important in its application to the arts of life. The detail of his experiments and conclusions, in which caution, simplicity, and precision are eminently conspicuous, was laid before the literary society in the university in 1762; formed a part of his annual course of lectures; but what seems altogether unaccountable, no published statement appeared from himself at any period of his life.

When the chemical chair in the university of Edinburgh became vacant in 1766, by the appointment of Dr Cullen to the professorship of medicine, Dr Black was again chosen his successor. Placed in a more conspicuous station, and attended by a greater number of pupils, which the high celebrity of the medical school of Edinburgh brought to his lectures, he was anxious to discharge the duties of a useful teacher; and his great object was to render his instructions intelligible to the least informed of his hearers. In the attainment of this object, no public teacher of any science ever succeeded better than Dr Black; his hearers were not only instructed, but delighted; and, by his agreeable manner, the study of chemistry became fashionable, and the knowledge of the science was rapidly extended. It has been remarked by his biographer, and with great truth, that in one point of view the effect of this was unfortunate for the progress of the science, the improvement of which he seems to have altogether laid aside, for what may be deemed by some the less important, but not less useful task of elucidating its elementary principles. Those who have had the good fortune to be the pupils of Dr Black, and who are able to appreciate his merits, will not hesitate in pronouncing him to have been one of the most perfect models of a public teacher. With a comely and interesting countenance, a fine and distinct voice, and a slow and graceful elocution, he exhibited in his lectures a degree of simplicity and elegance which has been seldom equalled and never surpassed; and, without any parade of apparatus, or ostentatious display of experiments, he confined himself to what was essentially useful for the illustration of the doctrines which he delivered

In the long period of 33 years, during which he held the chemical chair in the university of Edinburgh, although he scarcely added any thing by his own labours to the science, yet his reputation as a che-

Black.

mical philosopher never declined. This seeming indifference in promoting a science which he was so well qualified to cultivate and adorn, is ascribed partly to indolence, and partly to an enfeebled constitution, which precluded much exertion; but whatever were the cause, the fine specimens of philosophical investigation which he has left behind, must ever excite regret that his labours were not more varied and more extensive, in the wide field which was then occupied by a numerous band of successful inquirers, among whom it cannot be doubted that Dr Black's perseverance in his brilliant career would have still placed him in the first rank.

Dr Black's health had been in a declining state from the year 1793; a successor was appointed to assist him in his labours in 1796; in the following year he delivered only part of the course of lectures; and this was the last time that he appeared as a public teacher. On the 26th of November 1799, when he had reached the 71st year of his age, he died, without any convulsion or stupor to announce or retard the approach of death. "Being at table, with his usual fare, some bread, a few prunes, and a measured quantity of milk, diluted with water, and having the cup in his hand, when the last stroke of the pulse was to be given, he set it down on his knees, which were joined together, and kept it steady with his hand, in the manner of a person perfectly at ease, and in this attitude expired without spilling a drop, and without a writhe in his countenance, as if an experiment had been required to shew to his friends the facility with which he departed. His servant opened the door to tell him that some one had left his name; but getting no answer, stepped about half-way towards him, and seeing him sitting in that easy posture, supporting his bason of milk with one hand, he thought that he had dropped asleep, which sometimes happened after his meals. He went back and shut the door; but before he went down stairs, some anxiety, which he could not account for, made him return and look at his master. Even then he was satisfied, after coming pretty near him, and turned to go away; but returning again, and coming close up to him, he found him without life."

The only publications of Dr Black which appeared in his lifetime were, Experiments on Magnesia, Quick-lime, and Alkaline Substances; Observations on the Freezing of Water that has been boiled,—in the London Philosophical Transactions for 1774;—and the Analysis of the Waters of the Hot Springs of Iceland, in the Edinburgh Philosophical Transactions, Vol. II. Dr Black's Lectures, in two volumes quarto, a posthumous publication, for which the world is indebted to the care and diligence of his learned friend and associate, the late Dr Robison of the same university, cannot fail to be perused with pleasure and advantage by every student of chemistry who can be gratified with simplicity and elegance in the exposition of the science, and with peculiar aptitude and felicity of illustration drawn from the phenomena of nature or the processes of art.

The charge of plagiarism has been loosely and unguardedly brought by Dr Black's biographer, against several philosophers, in appropriating to themselves his beautiful discoveries concerning heat; and it is curious to observe with what earnestness this complaint has been propagated, even at the present day, especially against foreigners, among whom de Luc is accused of having arrogated to himself Dr Black's discovery of latent heat. In vindication of the character of that venerable naturalist, we were furnished with the means of stating the very reverse, and in the following extracts he expresses the most explicit acknowledgment of Dr Black's title to the original discovery: "Ne connoissant point le *feu latent*, dans la vapeur á toute temperature, *dont la premiere decouverte est due au* Dr Black." p. 102.—"Ce qui developpoit l'idée de *chaleur latente par laquelle le Dr Black avoit designé ce phenomene.*" p. 232.—"Le Dr Black ayant decouvert qu'une certaine quantité de chaleur disparoit, quand la vapeur de l'eau bouillante se forme, *nomma ce phenomene chaleur latente* dans la vapeur." p. 385.—*Introduction a la Physique Terrestre.*

Blackburne.

BLACK JACK, an ore of zinc, which is also denominated blende and false galena. See MINERALOGY.

BLACK LEAD, a mineral substance composed of carbone and iron, with a portion of earthy matter, is well known as the substance of which black-lead pencils are made, and is otherwise called plumbago and graphite. See MINERALOGY.

BLACK WAD is a term which is sometimes employed to designate black-lead or plumbago, and is sometimes applied to an ore of manganese. See MINERALOGY.

BLACK SEA, denominated also the Euxine, is an extensive inland sea which communicates with the Mediterranean by the straits of Constantinople, and is included partly within the limits of Europe and partly within the boundaries of Asia. It is conjectured by naturalists, with some degree of probability, that the Black sea formed at one time, by the accumulation of the waters of numerous rivers, an immense lake; and that the Aral and the Caspian, from the similarity of the fish which inhabit their waters, were parts of it. The only outlet which the increasing collection of this body of waters could force to itself, was the passage into the Mediterranean, by the Thracian Bosphorus. Extensive fisheries are established at the influx of the rivers into the Black sea; and a valuable trade has long existed between the mercantile adventurers of Europe and the east, in exchanging the productions and manufactures of different countries. The Black sea is often subject to tremendous storms, and in some parts of it the navigation is dangerous, from shoals and sand-banks.

BLACKBURN, a town of Lancashire in England, stands on the banks of the river Derwent, in a valley encompassed with hills, and, it is said, derives its name from the blackness of the water of the river. The population exceeds 15,000, and thriving manufactures of cotton, calicoes, and muslins have been established. The coal in the vicinity, and the advantage of extensive inland navigation, afford great facilities to the manufactures and trade of this place.

BLACKBURNE, FRANCIS, a learned English clergyman and theological writer, was born at Richmond in Yorkshire in 1705, and having finished his grammatical education was admitted, in 1722, a pensioner of Catharine-hall, Cambridge; and, after receiving clerical orders, was inducted to the rectory of his native town; and at a later period, 1750, was preferred to the archdeaconry of Cleveland, and to the prebend of Bilton. In the course of a long life, archdeacon Blackburne was not only assiduous in the discharge of his pastoral duties, but was the author of numerous works either with regard to the doctrines or forms of Christianity; and all his writings discover the marks of an intelligent mind, strongly attached to civil and religious freedom. Even his controversial treatises, divested of the asperity which often accompanies such productions, are distinguished by their decency and moderation, and afford both entertainment and instruction to the general reader. *General Biography.*

BLACKLOCK, Dr Thomas, a poet and clergyman of the church of Scotland, was born at Annan in Dumfries-shire in the year 1721, and was scarcely six months old when he was deprived of his eye-sight by small-pox. His love of literature appeared early; and his father, an intelligent mechanic, and other friends who were most frequently near him, fostered the inclination, by reading to him such books as were suitable to his age. The gentleness of his disposition, not less than compassion for his misfortune, encouraged them in these kind offices, and made them assiduous in their endeavours to promote his instruction and amusement. With their assistance he acquired some knowledge of the Latin language. He was delighted with poetry; and at the age of twelve composed a poem which appeared in the collection published after his death.

The marriage of young Blacklock's sister with Mr M'Murdo, an eminent brewer in Dumfries, and an accomplished man, was a fortunate connection for the young poet; it introduced him into better society,—afforded him at last the advantages of a liberal education,—and was some alleviation for the loss which he sustained by the sudden death of his father, who, in attempting to extinguish a fire which had broken out in his son-in-law's brewery, perished in the flames. This afflicting incident is pathetically lamented in the soliloquy which was composed soon after. The fame of Blacklock's genius and attainments had now spread beyond the narrow circle of his own friends and acquaintances; and the accidental visit of Dr Stevenson, an eminent physician in Edinburgh, at Dumfries, afforded that gentleman an opportunity of becoming acquainted with his talents, and of exciting an interest in his future destination. Under his patronage, Blacklock, then in his twentieth year, commenced his studies at the grammar school of Edinburgh; and continued to prosecute them, with his usual diligence and assiduity, till the flames of civil war burst out in 1745. During his residence in the metropolis he added the knowledge of the French language to his literary acquirements; and at this early period of his life appeared as an author, by the publication of a small collection of poems.

While the rebellion raged in the kingdom, Mr Blacklock retired to Dumfries, where he found an hospitable asylum in the house of his brother-in-law, and enjoyed the agreeable society of several intelligent men, whose acquaintance and friendship he had obtained. The return of public tranquillity permitted him to resume his studies in Edinburgh. Having completed the usual course of academical education, and the prescribed term for the study of theology, he was licensed to preach the gospel in the year 1759; and, as a preacher, the warmth of his piety, and the elegance of his compositions, soon procured him a high degree of celebrity among the more enlightened classes of society. Previously to this time a second edition of his poems appeared in 1754; and two years afterwards a quarto edition, encouraged by subscription, in which his celebrated countryman David Hume, and Mr Spencer, professor of poetry at Oxford, who prefixed an account of Blacklock's life and writings, took a deep interest, was published in London. Of Blacklock's assiduity and activity of mind, a striking example is recorded, in the plan which he projected of preparing a course of lectures on oratory for the instruction of public speakers, and particularly for those who were destined to the bar or the pulpit. Mr Hume, with whom he had contracted a close intimacy, was consulted, and, being doubtful of success, dissuaded him from the attempt; and then it is said the resolution was formed of devoting himself to the clerical profession.

A trying period of Blacklock's life now approaches. In the year 1762, through the interest of the Earl of Selkirk, he was presented to the church of Kirkcudbright. But, either from political animosities between his noble patron and the inhabitants of the borough, or the violent prejudices which then existed against church-patronage, or from the afflicting privation under which he laboured, and which his destined parishioners might suppose disqualified him, in some degree, for the discharge of his pastoral duties, or from the polished style or elegant composition of his discourses, which were not exactly adapted to common minds, or from the combined effect of all these causes, it soon appeared that a marked opposition was to be made to his reception in the parish. On the day of his ordination, he entered the town amidst the hisses and hootings of the populace; and with some difficulty he and his friends reached the church where the ceremony was to be performed. This cruel hostility inflicted a deep wound on his delicate feelings; and threw a dark gloom on the pleasing prospect which reason and fancy had pictured to his imagination, of happiness to himself and usefulness to others in his future labours. A protracted litigation of two years terminated in a compromise, by which he resigned the living, and accepted of a moderate annuity.

A short time before he was ordained, Mr Blacklock married Miss Johnston, the daughter of an eminent surgeon in Dumfries; a connection which proved the great solace and blessing of his future life, and afforded him, with all the tenderness of a wife, all the zealous care of a guardian and friend. With the slender provision which he received from the living which he had resigned, he removed to Edinburgh in 1764; and, for the period of twenty-three years, continued to receive into his house as boarders a number of young gentlemen, whose studies he assisted by his superintendence and advice. Soon after this

Blackmore. period, the degree of doctor of divinity was conferred upon him by the university of Aberdeen, at the recommendation of Dr Beattie, then rising into poetical fame, and an admirer of his genius. Dr Blacklock's advanced years, and declining health, required him, in 1787, to relinquish his labours in superintending the tuition of young men, and to indulge in that repose which was not to be found in a crowded family. Fits of despondency, to which he had been subject even in his earlier youth, recurred more frequently; and neither the kind attention of his friends, nor the unceasing care of a most affectionate wife, was able at times to counteract their effects on his spirits. After a week's illness, death removed him from all worldly cares in 1791.

Subject to the same privation, individuals with extraordinary powers and acquirements have appeared. Among these rare occurrences in the history of mankind, Dr Blacklock's genius shines conspicuous. The accuracy and beauty of description of visible objects, which adorn his writings, are not the least remarkable features in the works of Blacklock, who, it will be recollected, was deprived of his sight in early infancy. "Blacklock, (says a learned foreign critic,) to posterity will seem a fable; as to the present age he is a prodigy. It will be thought a fiction that a man, blind from his infancy, besides having acquired a surprising knowledge of Greek, Latin, Italian, and French, should at the same time be a great poet, and without having ever seen the light should, notwithstanding, be singularly happy in his descriptions." The poetry of Dr Blacklock is justly characterised by his biographer as breathing the purest spirit of piety, virtue, and benevolence; and his prose works are distinguished by just philosophical reflections and elegant composition.

BLACKMORE, Sir Richard, an English physician and poet, was a native of Wiltshire, and was born about the year 1650. Educated for some time in a country school, he was sent to Westminster in his thirteenth year, became a student at Oxford in 1668, and, after a long residence of twelve or thirteen years, is supposed to have left it without adding much to his stock of literature, at least this is inferred from the careless or inaccurate manner in which the ancient names of places or nations are introduced in his poems. Having travelled for some time on the continent, and having been admitted to the degree of doctor of medicine at Padua, he returned to England, and obtained high eminence and extensive practice as a physician in London. His residence was in Cheapside, and his friends were chiefly in the city. In the early part of Blackmore's time, as Dr Johnson remarks, a citizen was a term of reproach, so that the place of the physician's abode was a topic to which his adversaries had recourse in the penury of scandal; nor did they forget to publish, as another ground of reproach, that he had been compelled by indigence in some part of his life to undertake the humble, but surely not dishonourable, task of teaching a school,—the only reproach, it is observed by Johnson, in his strong but peculiar manner, which all the perspicacity of malice, animated by wit, has ever fixed on his private life.

It is not a little singular that the first production of Blackmore which was presented to the world was a heroic poem, *Prince Arthur*, published in 1695, in ten books, and written, as he relates, "by such catches and starts, and in such occasional uncertain hours as his profession afforded, and for the greatest part in coffee-houses, or in passing up and down the streets." In two years more, such was the activity of his fertile muse, *King Arthur*, another heroic poem, in twelve books, appeared. About this time he was appointed one of King William's physicians, and was raised to the honour of knighthood, with the present of a gold chain and medal. The malignity of the wits, by whom he was assailed from all quarters, ascribed these marks of royal favour to his new poem; but his good fortune is more justly to be attributed to his attachment to the principles of the revolution. On the accession of Queen Anne he was also appointed one of her Majesty's physicians. Blackmore continued to write to the end of his days, but the extensive practice which he enjoyed during part of his life forsook him towards its close, when he employed his unwelcome leisure in writing books on medical subjects, and endeavoured to teach others to cure those whom he could himself cure no longer. Exhibiting in his last hours unequivocal marks of the most fervent piety, he died in 1729.

Four heroic poems were the offspring of the prolific muse of Blackmore. Beside those already mentioned, *Eliza* and *Alfred*, the first in ten, and the second in twelve books, were the titles of the other two; and of these epic poems, it is observed, the first had such reputation and popularity as enraged the critics; the second was at least known enough to be ridiculed; the two last had neither friends nor enemies. *A paraphrase on the Book of Job, a Version of the Psalms, Creation, the Redeemer, a Satire upon Wit*, are enumerated among the poetical productions of Blackmore; beside which, he wrote the *Lay Monastery*, a periodical work, in the manner of the Spectator, various tracts on medical subjects, and even ventured into the difficult path of theological controversy, by writing two books against the Arians. The name of Blackmore, by the unceasing enmity of cotemporary wits, whose judgment has been hastily confirmed by the undiscriminating censure of succeeding critics, is proverbial for dullness. But some critics, both of his own age and among posterity, have been disposed to do him justice. His poem of *Creation* was commended by Addison; and Johnson pronounces, that "it wants neither harmony of numbers, accuracy of thought, nor elegance of diction; it has either been written with great care, or, what cannot be imagined of so long a work, with such felicity as made care less necessary. Its two constituent parts are ratiocination and description. To reason in verse is allowed to be difficult; but Blackmore not only reasons in verse, but very often reasons poetically, and finds the art of uniting ornament with strength, and ease with closeness. This is a skill which Pope might have condescended to learn from him, when he needed it so much in his moral essays. In his descriptions both of life and nature, the poet and the philosopher happily co-operate; truth is recommended by elegance, and elegance sustained by truth." Johnson's *Lives of the Poets*.

BLACKNESS is that quality of a body, or peculiar texture of its surface, in which the larger proportion of the rays of light is absorbed; and in this sense it is opposed to *whiteness*, or that condition of a body which reflects the greater part of the rays of light which fall upon it.

BLACKSTONE, Sir William, a celebrated English lawyer, was born at London in 1723, was educated at the Charter-house school, and in his fifteenth year was entered at Pembroke college, Oxford. Poetry and the fine arts seem to have occupied a considerable share of attention in his early years; for, at the age of twenty, he composed a treatise on architecture; and when he commenced the study of the law, which was now his destined profession, he expressed his regrets at leaving the flowery paths of classical literature for the less inviting details of legal research, in an elegant poem, entitled, *The Lawyer's Farewell to his Muse*, which afterwards appeared in Dodsley's collection. In 1741 he was entered in the Middle Temple, was elected a fellow of All Souls college in 1743, and was called to the bar in 1746. But as he was deficient in those popular talents which more certainly insure the success of a public pleader than less splendid but more substantial acquirements, he made so little progress in procuring employment that, after seven years attendance at the courts of Westminster, he determined to abandon this part of his professional practice, and to retire to his fellowship.

To supply a striking defect in the system of education in the English universities, Mr Blackstone prepared a series of lectures on the laws of England, and delivered the first course at Oxford in 1753; and he continued it for several years with much reputation. In 1758 he was elected the first Vinerian professor at Oxford, in consequence of an institution having the same view, which was liberally endowed by Mr Viner, for promoting the study of the municipal law in that university. His lectures acquired him great reputation, and encouraged him to resume his professional practice at Westminster hall; and, in this second attempt, it appears that he was sufficiently successful. In 1761 he obtained a seat in parliament, and two years afterwards was appointed solicitor-general to the queen. His marriage in 1761 required him to vacate his fellowship, on which he was nominated principal of New-inn hall; but he resigned this office, along with the Vinerian professorship, in 1766. In 1770, declining the office of solicitor-general, he was appointed a judge of the court of common pleas, which station he held till his death in 1780.

Beside some pieces of a local and temporary nature, he was the author of *Law Tracts*, a collection of treatises, some of which had previously appeared in a separate form, which was published at Oxford in 1762, in two volumes, the first of which contains an essay on Collateral Consanguinity, Considerations on Copyholders, and a treatise on the Law of Descents; and the second includes the Great Charter, and Charter of the Forest, &c. with an introductory discourse on the history of the charters. But the great work which has given celebrity to the name of Blackstone is, his Commentaries on the Laws of England, in four volumes, the first of which was published at Oxford in 1765. This valuable work comprehends the substance of his lectures, and is justly regarded as the most popular book on the municipal laws of England which has yet appeared. The industry and research, the accuracy and judgment which it displays, and the elegance and interest with which the subjects are treated, render it not only useful as an excellent elucidation of the laws of England to the professed student, but highly instructive to the general reader.

BLAIR, Robert, a poet and clergyman of the church of Scotland, was the eldest son of the Rev. David Blair, one of the ministers of Edinburgh; was born about the beginning of the 18th century; and having completed his academical studies in the university of his native city, and spent some time on the continent, he was, after his return, admitted, in 1731, minister of Athelstaneford, a country parish in the county of Haddington. In this retired situation, which afforded few incidents for biographical notice, he passed the remainder of his life. But, to his praise, it is recorded, that he was a serious and animated preacher, an accomplished scholar, with a fine taste and polished manners, and was greatly respected by all classes in his neighbourhood. He was much devoted to the study of some departments of natural history; and it would appear from the correspondence which he held with Mr Baker, the author of several works on the microscope, that he employed some part of his leisure in microscopical researches.

As a poet, nothing is known of the progress of Mr Blair in his devotion to the muses. His first poetical effusion which was presented to the public, was a poem to the memory of Mr Law, professor of Moral Philosophy in the University of Edinburgh, who was his relation, and whose daughter he afterwards married. This poem, although it is to be regarded as a juvenile production, displays much pathos and energy, expressed in simple and beautiful language. But the *Grave* alone, which has been long one of the most popular poems in the English language, is sufficient to confer a high degree of celebrity on the author. With the exception of the poetry of Milton, it has been pronounced one of the best pieces of blank verse in the language; and if a fine glow of sympathetic feeling, animated description, and striking imagery, be essential to poetical composition, and by their combined effects produce that magic charm which touches every bosom, the Grave of Blair is entitled to this high commendation.

This excellent poem was not published till after the author's death. Through the mediation of the celebrated Dr Watts, whose approbation it obtained, it was offered, in 1741, for publication to the London booksellers; but they declined it as a hazardous speculation; thus affording at once a decided proof of want of taste and literary enterprise. But surprise may cease, when it is recollected, that the sublime effort of the epic muse, the *Paradise Lost* of Milton, brought the author only fifteen pounds, and found few readers, till the criticisms of Addison examined its merits, and displayed its beauties. It is not a little remarkable, that the Grave was read and admired for nearly half a century before any thing

Blair.

was communicated to the public of the author. This seeming neglect is more to be wondered at, when it is known, that some of his relatives rose to the highest literary eminence; and, among others, the professional labours of his cousin, Dr Hugh Blair, might have led him, with an amiable and pardonable partiality, if partiality it might be called, to commemorate his virtues and illustrate his works. The first sketch of his life was drawn up by Dr Anderson, and is inserted among his *Lives of the Poets*. Mr Blair died in 1746, and was succeeded by another poet, Mr Home, the well-known author of the tragedy of *Douglas*. Of a numerous family, one of his sons, Robert, was eminent as a profound lawyer, and rose to the high rank of Lord President of the Supreme Civil Court in Scotland. His sudden and premature death, while he held that conspicuous station, excited the deepest regret for the loss which the country sustained of an upright and accomplished judge.

BLAIR, Dr HUGH, a distinguished clergyman of the church of Scotland, and celebrated author of sermons, and writer on belles lettres, was born at Edinburgh in 1718. His great-grandfather, descended from the ancient family of the same name in Ayrshire, was minister of St Andrews, and chaplain to Charles I. and was one of the most accomplished scholars of the age in which he lived. The father and grandfather were respectable merchants in Edinburgh; but the former being concerned in some of the ruinous speculations of the times, saw himself reduced in his pecuniary affairs, and was forced to retire from mercantile business, and to accept of an office with a limited income in the excise. Deprived of all prospect of paternal inheritance, young Blair found it necessary to trust to his own personal exertions, and for this purpose very early directed his views to the church as his future profession.

Having passed through a grammatical course of education, he was admitted in his twelfth year a student in the university of Edinburgh; and at this seminary he continued for the long period of 11 years, assiduously and successfully occupied in acquiring that knowledge which the duties of his destined profession required. An essay on *the beautiful*, which he composed as an exercise while he was a student in the logic class, was highly approved by the professor, was read in public at the end of the session, and was regarded as an excellent specimen of his talents for composition, and a favourable earnest of his future fame. About this time, it is said, Dr Blair adopted a plan of study which greatly contributed to the accuracy and extent of his knowledge, and which he continued to practise occasionally through life;—in making abstracts of the most important works which he read, and in digesting and arranging them under appropriate heads according to the train of his own thoughts, the facts thus collected were retained and fixed in his mind. In this manner he studied history; and in conjunction with some youthful associates he constructed a comprehensive scheme of chronological tables. At this time the university of Edinburgh numbered among her pupils, Dr Robertson, Dr Smith, Mr Hume, and others, who became afterwards conspicuous in the civil, the ecclesiastical, and literary history of their country. With such friends and associates Dr Blair lived in habits of close intimacy; and, from their example and conversation, he could not fail to extend his knowledge and improve his taste.

Having finished his academical course, he was licensed to preach the gospel in 1741; his first appearances in the pulpit secured to him the reputation of an eloquent preacher; in the succeeding year he was presented to the parish of Colessie in Fife; and another year had not elapsed when he was appointed to the second charge of the Canongate of Edinburgh. In this situation he spent eleven years, discharging the various duties of the pastoral office, and rising in reputation by the excellent compositions which he delivered from the pulpit. In 1754 he was removed to Lady Yester's, one of the churches of the city; and four years afterwards he was appointed to the High Church of Edinburgh, which his biographer has strangely characterised as the most important ecclesiastical charge in the kingdom, —a singular assertion of any station in the church of Scotland, where no distinction of rank exists, and no difference of influence or authority is permitted, except what arises from respectability of character or superior intellectual attainments.

Dr Blair had hitherto confined his literary labours chiefly to the composition of sermons, which had acquired for him so much merited celebrity among those who heard him from the pulpit, and extended his reputation when they were afterwards presented to the world. Two sermons preached on particular occasions, some translations in verse of passages of scripture for the psalmody of the church, and a few contributions to the Edinburgh Review, a publication begun in 1755 and conducted for a short time, it is said, by some of the ablest men in the kingdom, were the only productions of Dr Blair which had yet appeared. Having now some leisure on his hands, and unwilling to permit his talents and industry to be unemployed, he projected a scheme of lectures on composition; and he delivered the first course in the college during the session of 1759. His lectures were well attended and highly approved by those who heard them; and the applause with which they were crowned, and the influence of a recommendation to government, led to the endowment of a professorship of rhetoric and belles lettres in the university of Edinburgh, and to the appointment of Dr Blair to fill that office. When declining health required him to resign the active duties of the professorship in 1783, these lectures were published; and, as they exhibit the most decided marks of acute judgment, fine taste, and critical skill, have added much to the celebrity of the author.

About this time, some fragments of ancient poetry, ascribed to Ossian, appeared among the literary circles of Edinburgh, and attracted the notice of some of the first characters of the Scottish metropolis. At the solicitation of Dr Blair and Mr Home, the celebrated author of the tragedy of Douglas, Mr Macpherson was induced to publish them; and they took a warm interest in promoting the subscription, which enabled him to make a tour through the Highlands of Scotland, for the purpose of collecting the materials of Fingal, and of other poems which bear the name of Ossian. Whatever opinion may be formed of these extraordinary poems, or of the extraordinary manner in which they were ushered into the world, the dissertation of Dr Blair, which was published in 1763, spread the author's reputation throughout Europe, and for beauty of language, delicacy of taste, and acuteness of critical investigation, stands unrivalled.

The first volume of his sermons was published in 1777; three other volumes appeared at different intervals, and all of them received the undivided approbation of the public; they circulated rapidly wherever the English tongue extends, and were soon translated into almost all the languages of Europe; and in 1780, a more substantial reward than empty fame awaited the author, by the grant of a pension from government of L.200 a-year, which was continued to his death.

Dr Blair married in 1748 his cousin Catharine Bannatyne, daughter of the Rev. James Bannatyne, one of the ministers of Edinburgh. A son, who died in infancy, and a daughter, who lived to her 21st year, the pride of her parents, and adorned with all the accomplishments that became her age and sex, were the offspring of this marriage. His wife, who had shared his fortunes and his happiness for nearly half a century, died in the year 1795. These domestic afflictions could not fail to make a deep impression on his mind; but he bore them with the fortitude of a man, and the resignation of a Christian. His increasing infirmities had, for some years before his death, rendered him unequal to the labour of the public discharge of his official duties. But his habits of industry did not permit him to waste even the close of life in idleness. His last summer was devoted to the preparation of his fifth volume of sermons; and it is not unworthy of record, that the sermon on a life of dissipation and pleasure, was the last which he composed. Towards the end of December 1800, he was seized with his last illness; and after three days suffering, and retaining to the last moment the full possession of his mental faculties, he expired on the 27th, when he had reached the 83d year of his age.

Of the private character of Dr Blair, it is scarcely necessary to say that it was highly respectable. His conduct through life was marked by prudence, purity, and dignified propriety; and of his sermons, which are so universally read and admired, it is needless to add, that they will long remain durable monuments of the piety, the genius, and sound judgment of their author.

BLAKEA, Wild-rose, a genus of plants belonging to the class Dodecandria, of which the first discovered species is a native of moist shady places in Jamaica.

BLANC, MONT, a stupendous mountain of Savoy, the highest of the whole group of the Alps, and the most elevated land in Europe, has been distinguished by the appropriate appellation of *white mountain*, from the snowy mantle which constantly veils its lofty summit, and clothes its sides for many thousand feet from the top. The mountain terminates in a ridge, in a horizontal position, stretching from east to west, and sloping on the different sides with various degrees of rapidity; and the ridge, especially towards the west end, is so narrow, that not more than two persons can walk abreast. The surface of the snow is scaly, and in many places covered with a crust of ice, under which the snow is dusty and has little coherence; and the covering of snow is so thick that no rock is seen within 150 yards of the top. The prevailing strata of Mont Blanc are composed of granite; but in some places beds or masses of steatitic and schorlaceous rocks are observed. The height has been variously estimated by different naturalists at 15,304 feet, 15,662 feet, and 15,680 feet, or nearly three miles above the surface of the sea.

Clothed in a perennial wintry robe, and elevated among the bleak regions of the unceasing storm, the summit of Mont Blanc seems to bid defiance to the approach of the adventurous traveller. To scale its stupendous height was long regarded as a hopeless and impracticable task. The first attempt to reach the top was made by M. Couteran and some attendants in 1776. On the 13th of July of that year, he departed from the priory of Chamouni at 11 o'clock at night; having ascended to the height of 13,000 feet, he was compelled to abandon the arduous enterprise; and, after a most fatiguing and dangerous journey of 22 hours, returned to Chamouni. M. Bourrit, on the 11th of September 1784, reached a very considerable elevation; but the intensity of the cold obliged him also to relinquish the undertaking. An attempt by the same traveller, accompanied by M. de Saussure, in the succeeding year, likewise failed. Dr Paccard, a physician of Chamouni, along with some of the guides of the place, was the first who surmounted the difficulties of the ascent, and, after a journey of 15 hours, reached the summit of Mont Blanc; remained half an hour on this elevated spot, and experienced great uneasiness from the intense severity of the cold. In August 1787, M. de Saussure was also successful in this daring attempt. The fatigue of the ascent, and the rarity of the air, rendered respiration extremely difficult and laborious, even with the slightest exertion. A few lichens were the only indications of vegetation observed on the higher parts of the mountain; the beautiful moss campion, *silene acaulis*, Lin. disappeared beyond the height of 12,000 feet; and no animal whatever seems to have its permanent abode in these inhospitable regions. Two butterflies on the wing were seen near the summit, but it was supposed that they had been carried up by the violence of the wind.

BLANC MONT, a department of France, including the former Savoy, lying on the west side of the Alps mountains, and having the department of Leman on the north, and the department of Upper Alps on the south. The Arc and the Isere are the principal rivers; some metallic ores, as iron, copper, and lead, are abundant; and the population exceeds 282,000. Chamberry is the chief town. The operation of smelting iron is extensively conducted.

BLAST-FURNACE. See Furnace.

BLASTING OF ROCKS is an operation which is usually performed by the explosive force of gunpowder, for the purpose of separating a mass of rock

Blasting.

from the solid strata, or of reducing a detached mass to smaller pieces, for the convenience of removal, or to be applied to certain uses. In the usual mode of conducting this process, a circular hole is made in the rock, by means of a chissel, to the depth of 12 or 14 inches. The hole is filled to the height of a few inches from the bottom with gunpowder; the upper part is closely rammed with clay or small fragments of stones; a sharp pointed iron rod is thrust down to the gunpowder; and when it is withdrawn, the vacant space is either filled with gunpowder, to act as a train to what is deposited in the bottom of the hole, or a straw filled with gunpowder is inserted. By means of this train the gunpowder is kindled; and a slow burning match is so placed, that it shall communicate to the train after the workman has sufficient time to secure himself from the projected fragments of the stone. But by driving in the rammer forcibly, premature explosions have sometimes occasioned terrible accidents. Such dangers are completely obviated by introducing the straw along with the gunpowder, and filling up the hole with dry loose sand; and by this simple management the explosion is equally efficient. Quicklime has been proposed as a kind of substitute for blasting rocks. The lime is introduced into the hole when newly calcined, and when suddenly slaked with water, it is supposed that the expansive force produced by the increase of bulk would rend the stone in pieces.

Methods of blasting rocks without gunpowder have been practised. The method adopted in Wiltshire, is to undermine the rock for a yard in length and half a yard in depth, and having introduced straw or brushwood into the cavity, to set it on fire, the heat of which expands the air within the stone, and its elastic force bursts it into pieces. A simpler method is to kindle a coal fire on the top of the stone, as in the case of large rounded stones in fields to be brought under culture, and when it has become red hot where it is in contact with the burning coals, to dash cold water upon it; and in this way, by the sudden and unequal contraction, the stone is reduced to fragments. Where coal is abundant this method may be both effectual and economical.

Mr Knight has invented an apparatus for blasting logs of wood by means of gunpowder. The instrument is a hollow screw. An auger hole is made in the log to be split; a quantity of gunpowder is put into the bottom of the hole; the screw is fixed in it nearly to the gunpowder; a match, prepared in the usual way, is passed through the hole in the screw till it touch the gunpowder; and being set on fire, its explosive force tears the log asunder.

Blatta.

BLATTA, the Cock-roach, a genus of insects belonging to the order hemiptera, of which one species, the American cock-roach, seems to be naturalised in some parts of this country, particularly in sea-port towns, to which it has been brought along with imported goods.

BLEACHING.

Introduction

THE materials of which cloth is made, whether derived from vegetables or animals, as they are produced in nature are rarely in that state of purity which answers the demands of the more improved periods of civilized society. Exclusive of those substances which adhere to them in the progressive operations of their fabrication, and which are generally removed by simple washing in water, with some slight addition, they are intimately combined with certain colouring matters, which can only be separated by chemical processes, the effects of natural agents, or applied by means of art. Hence it is obvious, that the art of bleaching, from the French word *blanchir*, "to whiten," belongs to an age of luxury and refinement, and that it is in vain to search for its origin in the remote and barbarous periods of antiquity; and accordingly the improved state of the art is of modern date, and can be traced no farther back than the close of the 18th century, when chemistry, in the progress of its brilliant discoveries and endless applications to the purposes of life, was directed to an examination of its principles, and to the improvement of its practice.

Bleaching, in its more restricted meaning, is applied to the whitening of cloth, or the materials of which it is made, which are derived from vegetable substances; but in a more enlarged sense it may include the whitening of both vegetable and animal matters, and, with no great impropriety, may be extended to every detersive or purifying operation.

History.

History.—About the middle of the 18th century, the excellent fabric, and especially the perfect mode of bleaching Dutch linens, brought them into high repute in every part of Europe, and hence the name *Holland cloth* is not forgotten in this country at the present day. The most celebrated bleaching grounds of Holland were in the vicinity of the village of Bloemendaal, about three miles from Haarlem. The remarkable whiteness of their linen was ascribed to the lye-ashes of Muscovy, and to the water of the downs, which was said to be sea-water filtrated through banks of sand; but this must be a mistake, for sea-water could not become fresh merely by passing through sand. When the successful modes of bleaching at this establishment were compared with the less perfect processes which were attempted in other places, a groundless prejudice was excited that no perfect bleaching could be effected at a distance from the sea. But the cloth bleached at this place was not merely the produce of the manufactories in the vicinity. The greater part was made in Silesia, and, after being bleached at Haarlem, was sold under the name of Dutch cloth, or Hollands. About the same time all the linen which was manufactured in Scotland was sent to the same place to be bleached, and such goods were distinguished by the name of *Scotch Hollands*.

It is probable that the Dutch mode of bleaching was first introduced into Ireland, where it was long conducted on a larger scale than in any other part of the British dominions. The first attempt in Scotland was made by a native of that kingdom; but whether he acquired his knowledge of the art from the practice in his own country, or by direct communication with Holland, is not recorded. He established a work in the north of Scotland in the year 1749; and in the hope of completing at home the preparation of their goods for the market, some of the principal manufacturers entrusted him with the bleaching of their linens; but he failed in his processes, and the disappointed manufacturers were obliged to transmit their cloth to Holland to be cleared and finished. One whole season and the half of the next were occupied in bleaching another parcel, and with no better success; but the experience and observation of a few years enabled him to improve his processes, and he became at last an excellent practical bleacher; his industry and intelligence were rewarded with affluence; and to this enterprising individual the manufacturers of Scotland were indebted for the means of preparing their linens for the market without foreign aid.

The discovery of oxymuriatic acid by Scheele, in 1774, and the application of that powerful agent, by Berthollet and other French chemists, to the processes of bleaching, constitute one of the most remarkable eras in the history of the art; and the compounds of that substance with the alkalies and earths, which rendered its use safer and more commodious, especially the combination with lime, which was first proposed and successfully tried by Mr Tennant of Glasgow, have contributed in a high degree to its improvement and perfection.

The different kinds of stuffs which are to be purified or whitened, from the diversity of elements of which they are composed, require to be subjected to different processes, and the application of very different ingredients, in the operation of bleaching, according as they are of an animal or vegetable nature. It may be, therefore, convenient to treat of them under separate heads.

Chap. I. Of Bleaching Linen.

As the object of bleaching is to separate the colouring matter from the stuffs which are to be whitened, it is undoubtedly of great importance to investigate its nature and properties, for the purpose of applying the different processes according to just chemical principles; and perhaps this subject, which shall be slightly adverted to before entering on the detail of the operations of bleaching, is worthy of a larger share of the attention of those who are engaged in this valuable department of our manufactures.

Sect. I. *Of the Colouring Matter of Linen.*

The colouring matter of linen yarn or cloth which is to be removed by bleaching, is either naturally combined with the vegetable production during its growth, or unites with it in some of the operations to which it must be subjected in the progress of manufacture. A minute examination of the changes which it undergoes, from the period of the plant ripening to its fabrication into yarn or cloth, when it is put into the hands of the bleacher, would greatly assist in deciding this point. In the mean time, a slight sketch of some of the previous processes may be useful.

Steeping flax.—The first operation to which flax or hemp is subjected, after being ripe, is steeping or watering; the object of which is to separate the fibres, which are to be formed into thread, from the other parts of the plant. This object is accomplished by a kind of fermentation or decomposition, which the sap and wood of the plant undergo, while the fibres, are little affected by proper management during the operation. This process is conducted either by steeping the plants tied up in bundles in water, which is called *water-rotting*, or by spreading them out on the grass, and thus exposing them to the moisture and dew of the atmosphere, which is called *dew-rotting.* Without considerable precaution, the fibres of the plants sometimes receive considerable injury in this process; and, with a view to obviate this effect, an improved method of watering has been proposed, by which the time necessary for the process is greatly abridged. In this method, a weak alkaline lye is employed instead of pure water. The plants are introduced into a chamber of twenty or thirty feet square, and the steam of water impregnated with caustic soda is passed through them till the necessary change be produced.

By whatever process it is conducted, when the watering is finished, the plants are dried either by exposure to the air, or by the application of artificial heat. To separate the fibres from the enclosed wood, the plants are subjected to the operation of beating, which is performed either by manual labour with mallets, or on a large scale by means of machinery, and the tender wood being bruised or broken into small pieces, is separated by the operation of heckling. The remaining fibres are then fit for being spun into yarn.

Mr Lee's method.—Beside the colouring matter naturally combined with the fibres of the plant, it can scarcely be supposed that it should not undergo considerable changes in the process of watering; and when this process is carelessly conducted, the fibres themselves are injured in their texture. To obviate these effects, a method of preparing flax was lately proposed by Mr Lee, by which watering, and the consequent injury to the fibres, are avoided. According to Mr Lee's method, the woody part of the plant is broken to pieces by beating the stalks on fluted rollers, and in this way is fully prepared for the operation of heckling. The supposed advantages derived from this method, were, that the fibres are not exposed to any injury, and, according to the rash opinion of a chemist of some reputation, all the processes of bleaching would be completely superseded; but the experiments of many intelligent manufacturers in Ireland, who had adopted this method of managing flax, clearly proved that the fibres were shortened, and thus the fabric of the cloth was injured; and a well conducted series of experiments, under the authority of the Board for the Encouragement of Manufactures in Scotland, shewed, that the produce of flax was considerably less than by the common method. And whatever advantages were derived from Mr Lee's method, the process of bleaching was still found to be necessary.

Colouring matter.—It seems not improbable that a more rigid examination than has yet been attempted of the nature and properties of the colouring matter, might afford the means of improving the bleaching processes. The researches of the indefatigable Mr Kirwan have thrown some light on this subject. When linen cloth is steeped in an alkaline ley, a change is produced both in the cloth and the alkali. The cloth is deprived of part of its colouring matter, and the alkaline properties of the salt disappear. Some new combination, therefore, has been effected. To a portion of alkaline ley thus changed, or saturated with the extract of linen yarn, muriatic acid was added; the precipitate obtained being dried on a filter, became clammy to the feel like moist clay, and assumed a dark green colour; and it was insoluble in 60 times its weight of boiling water. Dried on a sand heat, it became of a shining black colour, and more brittle, but internally it remained of a greenish yellow.

A portion of the greenish precipitate being digested in rectified spirit of wine, was almost entirely dissolved, and communicated to the spirit a reddish hue; but distilled water being added, the solution appeared milky, and a whitish precipitate was formed. The solution of the black matter was conducted in a similar manner, and afforded nearly the same results. Neither spirit of turpentine nor linseed oil, even after long continued digestion, dissolved either the green or the black matter. The green matter communicated to sulphuric and muriatic acids a brownish colour, and to nitric acid a greenish tinge; but no other change was effected, for the quantity of matter was not diminished.

From these experiments it appears that the matter extracted by alkalis from linen yarn is a peculiar resinous substance, but different from pure resins by being insoluble in essential oils, in which property it approaches to the nature of lac. In the farther prosecution of these experiments, Mr Kirwan found that the colouring matter of linen yarn is soluble, either partially or entirely, in solutions of the alkalies, both in their pure state and in the state of carbonate; but that potash, whether pure or combined with carbonic acid, is the best solvent of this resinous matter.

Sect. II. *Operations of Bleaching.*

Steeping.—The first operation to which linen cloth is subjected is steeping; and this may be considered as chiefly preparatory. The object of this process is to remove the paste, or *dressing*, which is applied to the threads in weaving. This matter is separated by fermentation, to promote which, the pieces of cloth are immersed in water, of the temperature of 65° to 75° Fahrenheit, for about 48 hours. Having remained a sufficient time, the pieces are well washed in running water, either by treading with the feet or by means of machinery.

But in the improved process of steeping, the pieces, after being washed for several hours, to separate any loose matters which adhere to them, are introduced into a circular wooden vat, and are regularly disposed above each other, without being too much pressed together. The vat is then filled with the alkaline ley, at a blood heat, which has been employed in the bucking or boiling processes of other parcels of goods; and, to keep the whole immersed in the liquid, a piece of wood in form of a cross is fixed above them. A few hours only elapse when the temperature is increased, the liquid is enlarged in bulk, an intestine motion takes place, air is evolved, and a thick scum is formed on the surface. The period of fermentation varies from twelve to eighteen hours, according to the temperature of the air. But as soon as it ceases the linens must be removed, otherwise they are apt to be injured from the effects of the putrid fermentation which follows, and the colouring matter is at the same time more strongly fixed. The goods are then subjected to a second washing, to separate all the loose matters which adhere to them, and they are then prepared for the operation of bucking.

Bucking.—The next operation, after steeping and washing, is what is technically called *bucking*, and is one of the nicest processes in the art of bleaching. In this operation, the goods are introduced, as in the former, into a large wooden vat; and, from a boiler placed above the vat, the linens are covered with caustic alkaline ley at a blood heat. The ley having remained for some time on the goods, is let off by a stop-cock at the bottom of the vat into an iron vessel sunk in the ground, from which it is pumped up into the boiler, where the ley is raised to a higher temperature, and is again admitted to the goods in the vat, and from the vat it is let off into the iron vessel, and again raised by the pump to the boiler. The same series of operations is repeated till the alkaline solution is fully saturated with the colouring matter, and is also deprived of its causticity. This change is easily ascertained by the offensive smell which it assumes.

In this process it is of great importance, for the complete separation of the colouring matter, to attend to the gradual increase of temperature of the alkaline solution in its repeated applications to the goods: For when, by ignorance or mismanagement, the first application is made at the boiling temperature, the colouring matter, instead of being removed, is so strongly fixed that no after treatment can produce the desired purity.

Another necessary precaution, in concluding the operation of bucking, is to avoid washing the linens in cold water while they are hot, because a portion of the colouring matter is again fixed in them, which is not easily removed. To obviate this inconvenience, a stream of warm water is passed upon the goods, immediately after the saturated alkaline solution is let off. The soluble impurities are thus removed, after which a current of water is allowed to flow on the goods till it pass off nearly transparent. They are then washed and prepared for the succeeding operations.

The improvement proposed by Widmer in France, and varied by Mr Lowrie of Glasgow, in the operation of bucking, has greatly contributed not only to the economy of labour, but also to the saving of the materials employed, especially when it is conducted on a large scale. When the linens are introduced into the vat, and the boiler is filled with the alkaline solution, a pump moved by machinery raises the solution to a sufficient height above the vat to pass through four pipes pierced with small holes, or to fall on a broad plate of metal, through the perforations of which it is equally spread in a continued stream on the goods, and, by means of a valve which opens inwards, the ley, after having passed through the linens, returns to the boiler. As soon as the operation commences the fire is applied to the boiler, and the alkaline solution is gradually heated during its circulation through the goods in the vat, and when it begins to boil the operation of pumping is stopped by detaching the handle of the pump from the machinery, and the ley being forced from the close boiler through the pump, falls in a continued stream on the goods in the vat. The advantages of this improvement are obvious; as the operation is conducted by means of machinery, no danger arises from the inattention of the workmen; the gradual increase of temperature, and regularly repeated application of the alkaline ley, are more effectual in removing the colouring matter; and the quantity of alkali saved is estimated at one-fourth, and sometimes even one-third, of what is required in the former mode of conducting the operation.

Souring.—According to the older mode of bleaching, the process to which linen goods were next subjected was that of *souring.* The linens were steeped in milk which had become sour by spontaneous decomposition. This usually took place for the first time after the fourth or fifth bucking, and was called the first sour, when the whole operations of bleaching consisted of bucking, washing, and crofting, or exposing the goods on the grass. In this first sour the linens remained for two or three weeks, or till it was observed that the scum on the surface began to crack and subside. They were then subjected to a repetition of the other operations.

But as the acid obtained from the milk, or from the fermentation of farinaceous substances, was of uncertain strength, and at best produced but a feeble effect, the introduction of sulphuric acid, the strength of which could be exactly regulated, contributed essentially to the improvement of this operation, and to the abridgement of the time requisite to whiten goods for the market. By this improvement linens could be completely bleached in three or four months, which by the former method required seven or eight months; in proof of which it is only necessary to state, that the souring process, when sulphuric acid is employed, can be completed in eighteen or twenty-four hours, which, in the other method, was less effectually performed in four or five weeks.

In preparing the acid liquor, the sulphuric acid is introduced into a large wooden vessel lined with lead, and diluted with water till it is reduced to the strength of good vinegar. But the proper degree of strength is precisely ascertained by the use of the hydrometer. As the specific gravity of the acid is much greater than that of the water, the precaution should be observed of mixing them well together by agitation before the goods are immersed. When the steeping process is completed, the linens are drained, and carefully washed in pure water, that every part of the acid may be removed, otherwise they are apt to be injured when they are dried, because the water with which the acid is diluted is evaporated, and the acid remains behind and acts on the vegetable fibre.

Whatever effect the application of acids may produce in the bleaching process, whether they combine with the alkali, or with iron, or with some earthy matter, and thus form neutral salts, which are removed by washing, it is certain that there is no good bleaching without their use. A strong prejudice has indeed prevailed against the employment of acids, and it has received some support from the opinion of speculative chemists; but these are fully counteracted by the observation and experience of the practical bleacher, and a fair comparison of the state of the goods soured with the mineral or vegetable acid. It is well known that the omission of the use of acids to neutralize the alkali employed in the bucking operations, subjects the goods to injury when they are exposed to the rays of the sun. This effect never fails if they are laid on the grass, even after a single operation, without souring; and that part of the cloth thus corroded is called by the workmen *ley-burnt.*

Boiling.—In bleaching linen goods, boiling is employed when they are considerably whitened; the ley employed in this operation is made with pearl ashes, or with pearl ashes and a certain proportion of soap. In conducting this operation, a moderate heat should be applied; violent ebullition should be avoided, and the precaution should be observed of keeping the stuffs immersed in the liquid, that its action may be equal and uniform. Cast-iron boilers are used in the boiling operation, and they are furnished with a stop-cock at the bottom, for the purpose of letting off the waste ley.

Sect. III. *Of Bleaching with Oxymuriatic Acid and its Compounds.*

The discovery of oxymuriatic acid by Scheele, in 1774, forms one of the most remarkable eras in the history of bleaching. But although its property of destroying vegetable colours was observed by that eminent chemical philosopher, the application of this active substance to the art of bleaching was not known till ten years afterwards, when the subject was successfully investigated by Berthollet, and its importance in bleaching was fully established. Chaptal, whose labours in the application of chemistry to the arts of life have developed the nature of many important processes, directed his attention to ascertain the properties and use of oxymuriatic acid in bleaching, about the year 1787; and about the middle of the same year, in consequence of a communication from Professor Copland, of Marischal college, Aberdeen, who had witnessed experiments with it at Geneva, to Messrs Milne, of the house of Gordon, Barron, and Company, Aberdeen, they seem to have been the first who employed it in bleaching in this country. But although they were fully satisfied of its efficacy and safety, they limited its use to the bleaching of such goods as the demands of the market did not permit to be subjected to the usual more tedious processes.

In the succeeding year, Dr Taylor of Manches-

Of Linen.

ter, in conjunction with Mr Cooper of the same place, instituted a most decisive experiment to ascertain the use of oxymuriatic acid in bleaching; for by its application an entire piece of cotton cloth was bleached, printed, and prepared for the market in less than three days. The favourable result of this experiment led to the establishment of an extensive bleaching concern near Bolton in Lancashire. In 1789, a detailed account of the construction of the apparatus for preparing the new bleaching liquor, and the mode of applying it to use, was published by Berthollet; and the practice of chemical bleaching was then followed in different parts of France. As it frequently happens in the application of new substances, where even the most cautious observer is apt to overlook some circumstances in the process, many difficulties arose in the first employment of oxymuriatic acid in bleaching. In some cases the cloth was injured; and when the texture remained perfectly sound after the bleaching was completed, it assumed a yellowish shade after an interval of some weeks. But by care and attention in its application, the safety of the fabric was completely preserved; and the alternate use of the acid and alkaline solutions produced a perfect and permanent white. This is to be understood of bleaching cotton goods; for the yellowness of linen cloth can only be removed by exposing it for some time on the grass.

The celebrated Mr Watt of Soho, when on a visit in France, having seen the experiments with the new processes repeated by Berthollet, introduced this method of bleaching into the extensive establishment of his friend Mr Macgregor, at Glasgow; and in the first attempt 500 pieces of goods were finished.

The first application of the oxymuriatic acid was in the state of gas, and the first useful combination of that substance, for the purpose of bleaching, was with potash. This compound was first prepared by a company at Javelle near Paris, and hence it was denominated ley or liquor of Javelle; and it was announced as having the property of bleaching cloth by immersion for a few hours only. Some of the partners in this concern, with the hope of encouragement for the manufacture, settled at Liverpool, and applied to Parliament to secure to themselves the right of the invention. They failed in their application, on the ground that the discovery was not new. The manufacture was continued for some time; but as it was inconvenient to carry it to a distance in the liquid form, and as it was besides subject to a diminution of its strength by the action of the light and air, the demand gradually ceased, and the establishment was finally abandoned. Mr Foy, one of the operators in the manufactory, proposed to the principal bleachers for a suitable premium to assist them in the construction of the requisite apparatus, and to instruct them in the preparation of this liquor for themselves, and by his means the use of oxymuriate of potash became pretty general. Mr Tennant of Glasgow proposed oxymuriate of lime as a substitute for the compound with potash, and, in the year 1798, obtained a patent for this new bleaching liquor, the cheapness of which offered a material advantage to the manufacturer; but being in a liquid form the objection to the carriage of a bulky commodity was not removed. To obviate this objection, the right of preparing the liquor at their own works was communicated for a stipulated premium, and the new method of bleaching became still more general; but the validity of the patent was afterwards disputed, and, after a legal discussion, it was set aside. Mr Tennant's right to the advantages from the preparation of the oxymuriate of lime in the solid form, it is proper to observe, remains entire.

Preparation of oxymuriatic acid.—In the preparation of oxymuriatic acid for the use of the bleacher, various proportions of the materials employed have been recommended. In explaining the construction and principle of the apparatus for its distillation, Berthollet proposes six ounces of black oxide of manganese, one pound of common salt, and 12 ounces of sulphuric acid, diluted with an equal quantity of water. Bleachers in general employ a redundant proportion of materials, the reason of which perhaps is, the inequality of their strength or properties. The most common proportions for the production of this acid in this country, are equal parts, by weight, of sea salt and manganese, which are either carefully mixed together, or, with the addition of a little water, brought to the consistence of a thick paste. The quantity of sulphuric acid employed is equal to the weight of the other materials, and it is diluted with its bulk of water. When it is cool, it is poured upon the salt and manganese which have been introduced into the retort for the process of distillation; but it is supposed that the proportion of some of the materials in this mode of preparing the acid is too great; two-thirds of the sulphuric acid are reckoned sufficient for the purpose, and the quantity of manganese is also superabundant. The proportions recommended by Mr Rupp, are three parts of manganese, eight of common salt, six of sulphuric acid, and twelve of water; but Mr Tennant proposes equal parts of manganese, salt, and sulphuric acid, and the quantity of water to be equal to the bulk of the sulphuric acid. This, however, it is obvious, must depend on its strength. In Ireland, six parts of manganese with the same quantity of common salt, and five parts of sulphuric acid, diluted with five parts of water, are the most common proportions.

Oxymuriate of potash.—The combination of oxymuriatic acid with potash, which was effected by Berthollet about the year 1788, and by Mr Higgins of Dublin about the same time, was an essential improvement in the application of oxymuriatic acid to the purposes of bleaching. It is somewhat slower in its operation, but its effects are not less certain, and the manipulations of the workmen, in consequence of its offensive smell being obviated, are far less disagreeable. The following are recommended as the proportion of the ingredients for the prepara- of this saline compound: A receiver of sixty gallons capacity, English wine measure, is filled with a solution of caustic potash whose specific gravity is about 1015; a mixture of seven pounds of black oxide of manganese, and ten pounds of common salt, is brought

2

to the consistence of thick paste with the addition of a little water, and, being intimately incorporated, is introduced into the retort of the distilling apparatus. The head of the retort is then secured in its place. Eight pounds of sulphuric acid are gradually diluted with an equal weight of water; and when the mixture cools, one half of it is poured into the retort by means of a leaden funnel, through a small opening, which is immediately secured by a plug of lead, to prevent the escape of the gas, which is copiously evolved the moment that the diluted acid comes in contact with the mixture of salt and manganese. The sulphuric acid combines with the soda of the common salt, the muriatic acid is set free, and, according to the older chemical explanation of these changes, unites with the oxygen of the manganese; and in the form of oxymuriatic acid gas, as it passes through the solution of potash in the receiver, enters into combination with the alkali, and produces the oxymuriate of potash. It is usual to commence this operation in the evening; and in the morning when the distillation diminishes, the remaining half of the diluted sulphuric acid is introduced, an increased evolution of gas takes place, and when it again falls off the temperature is increased by means of a water bath; and when the process is finished, the solution of oxymuriate of potash is drawn off from the receiver, and applied to use.

Oxymuriate of lime.—Mr Tennant's patent for the preparation of liquid oxymuriate of lime being set aside, as already noticed, that solution is usually prepared by the bleachers themselves, the proportions of the materials originally directed by Mr Tennant are, 30 pounds of common salt dissolved in 140 gallons of water, wine measure, the object of which is to increase the specific gravity of the water, and the solution being completed, 60 pounds of quick lime in the state of an impalpable powder are added; 30 pounds of oxide of manganese, well incorporated with an equal weight of common salt, are introduced into the retort, and 30 pounds of sulphuric acid, previously diluted with 18 pounds of water, are poured upon the mixture. The distillation is conducted in the usual way, but it is recommended that the contents of the receiver be constantly agitated, to prevent the lime from subsiding.

But the preparation of oxymuriate of lime in the solid form, for which Mr Tennant still retains the exclusive privilege, is another essential improvement, because it can be conveyed to a distance at a trifling expence. When it is applied to use, the concrete compound is dissolved in water by agitation, and any insoluble matter contained in the lime is allowed to fall to the bottom, and the liquor to become transparent. Before it is applied to the purpose of bleaching, it is still more diluted with water.

The application of oxymuriatic acid gas, in combination with potash or lime, to the purposes of bleaching, is attended with very essential advantages; for although the process be less rapid, yet its gradual effect in destroying the colouring matter and whitening the goods is not less effectual, while at the same time it is neither offensive nor injurious to the workmen who are engaged in the business, or to those who superintend the operations.

Oxymuriate of magnesia.—This compound has been found highly beneficial in bleaching the white grounds of printed cloth, and at the same time retaining the different shades of colour unimpaired. In preparing the oxymuriate of magnesia, the earth being reduced to as fine a state as possible, is diffused in water and put into the receiver of the apparatus which is usually employed in the distillation of oxymuriatic acid. One part of manganese is introduced into the retort, and two parts of muriatic acid, of 1200 specific gravity, diluted with an equal bulk of water, are poured on the manganese; the operation commences, and the oxymuriatic acid gas, as it passes off, combines with the magnesia, which is kept diffused in the water of the receiver by occasional agitation; when the process ceases, and the insoluble impurities have subsided, the transparent liquor is drawn off.

Strength of bleaching liquors.—In extensive bleaching establishments, where the consumption of expensive materials, even by the most careful management, is very great, economy in their use must always be of great importance. It is also a matter of no small consideration to bring the substances which are employed in the different processes to the requisite degree of strength, to avoid, on the one hand, an unnecessary waste of labour by a repetition of the operations, and to obviate any risk of injury to the texture of the stuffs to be bleached. The strength of simple alkaline solutions may be ascertained with sufficient precision by determining their specific gravity by means of the hydrometer; and all that is necessary in the application of the alkaline leys, that they may produce their full effect, is to render the alkali employed as caustic as possible, and then to reduce it to that state of dilution which the particular stage of the process requires. The same remark is equally applicable to the strength of the souring liquor, particularly when sulphuric acid is employed.

But in using some of the compounds of oxymuriatic acid, the test of the specific gravity is not equally to be depended on, because, from the complicated action of the different ingredients in the compound, new substances, which indicate the same specific gravity in the solution, make their appearance, and produce very different, and often injurious effects on the stuffs subjected to their operation. In ascertaining the strength of the solution of oxymuriate of lime, the test of the specific gravity as it is indicated by the hydrometer is not alone to be trusted, because a solution of muriate of lime may have the same specific gravity, and not only produce a feeble effect in the bleaching process, but may be actually injurious; for it has been found by experiment, that the fabric of linen cloth boiled in this solution is greatly impaired. Beside the specific gravity, therefore, the property of the solution in discharging vegetable colours must be attended to. To ascertain the proper degree of strength, a solution of indigo in sulphuric acid is employed. In preparing this solution, one part of the indigo, reduced to a fine powder, is digested for several hours on a water bath, with eight parts of concentrated sulphuric acid; when the solution is completed, a thousand parts of water are added. One measure of this solution is introduced into a graduated glass tube, and the bleaching liquor, whose strength is to be ascertained, is poured in till the colour entirely disappears. In this way the number of measures of the bleaching liquor requisite to destroy the colour of the indigo is determined; and when the effect of any bleaching liquor on cotton or linen goods has been ascertained by experiment, and when it is known at the same time what number of measures of the same liquor is necessary to destroy the colour of the solution of indigo, the artist can always command a simple test to regulate the preparation of his liquors at any determinate strength. An improvement of this test has been proposed by Mr Rupp, who employs an acetate of indigo, which is prepared by adding a solution of acetate or sugar of lead to a solution of indigo in sulphuric acid, as long as any precipitate is produced. The sulphate of lead, which is insoluble, falls down, and the acetate of indigo which remains in solution, is poured off and preserved for use. An infusion of cochineal is employed by some for a similar purpose.

Bleaching with oxymuriate of lime.—When oxymuriate of lime is employed in bleaching linen goods, they are subjected to the same preliminary operations as in the old method. The bucking operations are carried on to the fourth or fifth time; but instead of crofting or exposing the goods on the grass for a certain time between each bucking operation, they are subjected to washing with abundance of water. They are then immersed in the solution of oxymuriate of lime; and after being washed with pure water, they are introduced into the souring vessels, again washed in water, and afterwards boiled in the alkaline solution.

For linen goods, three immersions at least in the solution of oxymuriate of lime are necessary. These immersions are followed by the alternate operations of souring and bucking, and between each of the individual processes the goods are to be well washed in water.

When linen stuffs are bleached by this method, they assume a yellowish colour, for the removal of which it is necessary to expose them to the air for a few days. The last operation to which they are subjected is boiling for a short time in a diluted solution of pearl-ashes and white soap. This operation is not only necessary for finishing the goods, but tends to destroy the disagreeable smell which usually adheres to those stuffs which are bleached by oxymuriatic acid, or any of its compounds.

Sect. IV. *Bleaching by Steam.*

Bleaching by steam, which, it is said, has been long practised in eastern countries, was first proposed by Chaptal in a memoir published in 1801, a translation of which soon after appeared in our own periodical works. This method was tried near Paris and in Ireland about the same time. M. Bawens, the proprietor of the manufactory of cotton thread and stuffs, near Passy in France, made the first trial on 1500 ells of cloth intended for printing; and the result of the experiment proved highly satisfactory. The following directions for the management of this operation were given by Chaptal. The cotton, disposed in handfuls, is first impregnated with a weak solution of soda which has been rendered caustic by lime; the cotton is trod down in a wooden or stone trough containing the alkaline liquor; and when it is uniformly penetrated, it is piled up on a wooden grate within a copper boiler; the redundant liquor flows through the bars of the grate into the boiler, and forms a stratum of fluid, which allows the mass to be heated, without any risk of burning either the cotton or the metal of the boiler. This arrangement being made, the apparatus is closely shut up to prevent the escape of the steam. The fire in the furnace is lighted, and the heat is continued till the whole of the liquid in the boiler has been converted into vapour, the temperature of which, from its compression in close vessels, is higher than that of boiling water, and produces a proportional effect in whitening the cotton. After being exposed to the steaming process, which in some cases is continued for thirty-six hours, the cotton is carefully washed, and exposed on the grass for a few days, when it assumes a great degree of whiteness; but if any coloured portion remain, a repetition of the steaming operation, and of exposure to the air, removes it.

This method of bleaching is not confined to cotton goods. A very successful experiment was made, at the suggestion of Chaptal, at the manufactory of M. Bawens, when 200 pairs of linen sheets, from the hospital of Hotel Dieu, were scoured and whitened. In the first experiment, 130 sheets were impregnated with an alkaline ley, containing one hundredth part of soda, were exposed for six hours to the action of the steam, again impregnated with the alkaline solution, and exposed for six hours more in the steaming apparatus. The same operation was repeated a third time; and the clothes being rinsed in water, with the addition of a small proportion of soap, were completely freed from every kind of spot or stain, and appeared of a pure white colour. In a second experiment, a smaller proportion of soda was employed, but with the addition of soap; and the cloth being treated in the same way the results were still more satisfactory. The advantages of this method appeared very considerable, both with regard to the saving of time and expence. By numerous trials which have been made in bleaching goods by this method since it was first announced, it has been found, that five steepings in the alkaline solution, with the alternate operation of the steam-bath, are sufficient for bleaching cotton goods; but nine steepings in the alkaline ley, with the same number of steaming operations, are requisite for whitening linen stuffs. It has been properly suggested, that the method of bleaching by steam may be essentially aided by an occasional immersion of the goods in some of the compounds of oxymuriatic acid. The objection which has been started against bleaching by steam, from the danger of the apparatus bursting by the elastic force of the confined vapour, is not worthy of any attention. To what dangers are not workmen exposed in a thousand other operations, which are not less hazardous when the proper precautions to avoid injury are not observed.

It appears somewhat unaccountable, that after the detailed description of the mode of bleaching by steam, which was published both in the French and British periodical works, and the distinct view of the whole process which is given in O'Reilly's Essay on Bleaching, a patent was granted, after the lapse of a few years, to a bleacher in Dumbartonshire in Scotland, for the exclusive right of a process exactly similar.

Chap. II. Of Bleaching Cotton Stuffs.

The colouring matter which adheres to cotton when it is obtained from the plant on which it is produced, seems to be somewhat of an oily nature. This greasy matter is removed by steeping it in a weak alkaline ley, and afterwards washing it well in running water. But however perfectly the washing is performed, a small portion of earthy matter still adheres to the fibres of the cotton. This matter is easily removed by the use of a diluted solution of sulphuric acid in water, and an after washing in pure water to remove the redundant acid.

Sect. I. *Of Bleaching Muslin.*

The coarser kinds of muslin, after steeping and washing, are boiled in a weak solution of pearl-ashes, and after a second washing they are twice boiled with soap alone; they are then subjected to the souring operation; and after being well washed, to remove the whole of the acid, they are again boiled in soap, and after another washing, they are immersed in a solution of oxymuriate of potash. The boiling in soap, and the immersion in the oxymuriate of potash, are again repeated, until the goods have acquired the requisite degree of whiteness, when they are last of all soured, and washed in pure water. The same processes are followed in bleaching the finer kinds of muslin, excepting that soap only is employed in the boiling operation, because the pearl-ashes are apt to injure the texture of the cloth when it is of a very fine fabric.

Coloured goods.—In bleaching cotton cloths, in which fixed colours, such as turkey red, or indigo blue, are dyed in the yarn before it is manufactured into cloth, much precaution is necessary; and before the effects of the different ingredients were understood by the practical bleacher, no small degree of uncertainty prevailed in the result of the processes to which the goods were necessarily subjected. Cotton stuffs which have permanent colours are first steeped and washed in cold water, and after being boiled with soap, and a second washing, they are immersed in a solution of oxymuriate of potash of moderate strength; the same processes are repeated till a pure white colour is obtained, and the operation is finished in the usual way by souring and washing. In this manner, by proper management of the different operations, the colours are so far from being injured, that they are greatly improved in delicacy and brilliancy.

Ginghams, or other stuffs of which the yarn of the white part has been previously bleached, require fewer operations; after being steeped and washed, to remove the paste or dressing, they are again washed and slightly boiled with soap, rinsed in pure water, soured, and washed.

Drying muslin.—In extensive bleaching establishments much inconvenience and delay arose in bleaching large quantities of muslin, especially in the winter season, and when the time for finishing them for the market was limited, from the want of sufficient means for drying the goods. An ingenious contrivance of Mr Burns of Paisley completely obviates this inconvenience, and enables the manufacturer to bring his goods to the market at all seasons of the year, however unfavourable may be the state of the weather. Mr Burns's discovery consists in the elegant application of a beautiful chemical process, in which great dispatch and perfect safety to the goods are happily combined. The apparatus for conducting this operation is equally simple as the process itself. Hollow cylinders of tin plate are prepared, of such a length as to correspond with the breadth of the cloth to be dried, the pieces of muslin are rolled upon these cylinders, which are then filled with the vapour of water, and are so contrived that the escape of the steam is precluded. The chemical reader will be at no loss to perceive the change which takes place, and the effect of this fortunate application of science to the purposes of art. The large proportion of heat which retains the water in the state of vapour, is given off to the cylinder, and the wet cloth which is wound upon it. The moisture of the cloth is converted into vapour, and is driven off, or, in other words, the cloth is dried. Deprived of its heat, the steam or vapour confined within the cylinder returns to the state of water, and the temperature of the apparatus is consequently diminished; and when this happens, the water is let off, and the cylinder is charged with a new portion of steam.

Sect. II. *Bleaching Cloth for Calico Printing.*

In bleaching cloth which is to be printed, a less pure white is required, but at the same time the stuffs must be perfectly freed from the colouring or other matter, which would prevent the goods from receiving and retaining the colours with which they are to be printed. The alkaline ley in which the stuffs are to be bucked, should be made moderately caustic by means of quicklime, that the fabric of the cloth may sustain no injury, and the solution should remain at rest for some time till it become quite transparent; for if any particles of lime remain in it, and be fixed on the cloth, the colour of those parts which are to be left white never retains the requisite clearness.

When linen cloth is to be prepared in this manner for printing, ten or twelve bucking operations with the alkaline ley are necessary. Between each operation it is well washed, and exposed for some time on the grass; at the end of the sixth bucking it is immersed in the souring liquor, and the same process is repeated as the concluding operation, when it is supposed to be sufficiently white for the purpose of printing.

Test of bleaching for calico printing.—It is extremely convenient for the manufacturer to have an easy test, which enables him to determine when the cloth is sufficiently bleached for printing. This is easily ascertained by cutting off a small stripe from the end of one of the pieces, and printing with the mordant which is to be employed in fixing the colour. It is then allowed to remain for some time that the mordant may adhere to the fibres of the cloth, after which it is well washed to remove the redundant particles, and then introduced into a weak madder bath, the heat of which is gradually increased, and the cloth is alternately immersed and exposed to the air, till the depth of shade required be obtained. If the bleaching process be properly conducted, that part of the cloth to which the mordant was applied combines with the colouring matter of the madder; but if those parts of the cloth which are intended to remain white assume a faint red hue, the bleaching process is imperfect and must be resumed.

As in other cases the bleaching of cotton cloth for calico printing is a less tedious operation, the same processes are followed, but a less quantity of materials is employed in the solution; five or six bucking operations are generally sufficient, and the same test to ascertain the perfection of the bleaching may be adopted.

In Lancashire the boiling is usually continued for eight or ten hours; and the same process, with the intervention of thorough washing, is repeated two or three times. After the second boiling, some bleachers subject the goods to the souring process, while others defer it till after the fourth or fifth boiling. In repeating the boilings, the strength of the alkaline ley is diminished at every succeeding operation. The cloth is then exposed on the grass for two or three days; but as a substitute for the exposure, or to abridge the time, it is immersed in oxymuriate of lime for about twelve hours, after which it is soured with sulphuric acid diluted with forty times its weight of water. Careful washing with successive portions of water is then practised, after which the cloth is hung up in the drying-houses, through which a current of atmospheric air constantly flows.

As cloth of a finer fabric is usually employed for printing with finer and more delicate colours, it is found necessary to repeat the boiling process oftener, and generally once or twice more; but the solution of potash employed is still more reduced in its strength for these additional boilings. In some bleaching establishments, where cloth is prepared for calico printing on a large scale, the pieces are subjected to powerful pressure after each process of bucking, souring, or bleaching. In some works the cloth is passed through a pair of wooden rollers, of sycamore or plane tree; and in others, the powerful agency of Bramah's hydrostatic press is employed for the same purpose. By this pressure the remaining liquor is forced out along with the impurities which have been loosened from the fibres of the cloth by the previous process, and all the pieces are brought to a uniform state of dryness.

The method of bleaching calicoes for printing, in some parts of Scotland, is somewhat different; the goods are first steeped in pure water, and then passed through rollers to force out the loosened impurities. After four boilings, for ten or twelve hours each time, in a caustic alkaline ley of the specific gravity, from 1.0127 to 1.0156, and alternate washings, they are immersed in a solution of oxymuriate of potash, of the specific gravity of 1.0625, which is still farther reduced in strength by the addition of twenty-four times its bulk of water. Having remained about twelve hours in this solution, the goods, while yet wet, are sometimes exposed on the grass for two or three days, and after being five or six hours in the souring liquid they are completely washed. After four more boilings, with alternate washings, they are again steeped in the diluted oxymuriate of potash, and being again well washed are passed through the souring liquor for half an hour. The last operation is a repetition of the washing with abundance of pure water, after which the goods are placed in the drying sheds without artificial heat.

Bleaching printed calico.—Those parts of printed cloth which remain white, have seldom that clearness and purity of colour which are required, and must therefore undergo some process of bleaching before it is fit for the market. This dullness is supposed to arise from the previous imperfect bleaching, or from a portion of the mordant adhering to the fibres of the cloth while in the water bath. On account of the delicacy of the colours which are applied to calicoes, powerful re-agents cannot be employed in whitening the unprinted parts. The oxymuriate of lime is altogether inadmissible, because it affects all the colours, and entirely discharges some of them. The oxymuriate of potash, when employed in a very diluted solution, is less active in its effects, but still it diminishes the intensity of the colours. It is therefore a matter of great importance in bleaching printed calicoes, to employ a substance which, without impairing their brilliancy, shall completely clear the white grounds, and also save the time which was formerly required of exposing the goods on the grass. For this purpose the oxymuriate of soda has been successfully employed. The solution is copiously diluted with warm water, and the maddered pieces are introduced into it, and allowed to remain till the white grounds are completely cleared.

The oxymuriate of magnesia has been employed for the same purpose with still better success; for, while the brilliancy of the colours is fully retained, the white ground is thoroughly purified. This compound, the method of preparing which has been already noticed, is dissolved in water raised to the temperature of 165° Fahrenheit, in such quantity as shall just afford a perceptible taste to the solution, which being well agitated, the printed goods, after being slightly browned, are rapidly run over a winch into the copper, and the operation, which usually requires only a few minutes, is continued till the ground is of a pure white. The cloth is then washed in a stream of water, that the adhering particles of the saline compound may not injure the colours. By adding a small proportion of the salt into the solution, the same process may be repeated on other parcels of the printed goods.

Test of good bleaching.—The prejudice which at one time was very strong against the new method, or chemical bleaching, as it is called, is perhaps not yet entirely removed; but beside the advantages in the saving of time and labour, and, in consequence, of the improvement of the processes since its first introduction in the saving of materials, it ought to be generally known, that the actual waste of the cloth itself by the old practice was not less than from 33 to 35 per cent.; but by the new method it rarely exceeds 26 or 27 per cent. This excessive waste, it is obvious, must have arisen from the tedious operations, and from the long exposure on the grass to which cloth was necessarily subjected in the older method of bleaching; but at the same time it must be admitted, that, from carelessness or inattention in the use of the very active substances which are employed by the modern bleacher, the risk of injury to the fabric of the cloth is considerable; while, on the other hand, under the direction of an intelligent superintendant, who is acquainted with the nature and property of the re-agents which he employs, and with the ordinary attention of the workmen, the whole process may be conducted with the utmost safety to the texture of the goods.

But for the satisfaction of the purchaser and consumer, it is extremely desirable to have a certain test of cloth being bleached without injury. A test of this kind is employed by the manufacturers of thread and cotton stockings in England. A thread of a very dark blue colour, or of turkey red, is run along the head of each stocking, and when the bleaching is properly managed, a perfect white is obtained, while the brilliancy of the colour is undiminished; but if the re-agents employed, particularly the oxymuriate of lime, be of excessive strength, the colours are impaired, and the texture of the goods, it is probable, is likewise injured. A test of the same kind has been judiciously recommended for all kinds of goods; and it has been proposed, that a line of coloured thread should be run along the edge of the cloth for this purpose.

Sect. III. *Bleaching of Hosiery.*

The preliminary operation in bleaching linen or cotton stockings, is to free them from the oily matters which are employed in weaving. For this purpose they are scoured in a scalding hot solution of soap in water, and afterwards well washed in pure water, which is to be renewed till all the impurities are removed. They are then boiled in an alkaline ley composed of one pound of American pearl-ash to one hundred gallons of water. After being boiled in this weak solution, they are washed in pure water, and then immersed in the solution of oxymuriate of lime, in the proportion of seven or eight quarts of the liquid, as it is distilled, to twenty gallons of water; and after remaining an hour and a half, or two hours, they are well washed in cold water, again immersed in the bleaching liquid, and again boiled in the alkaline solution. The alternate operations of steeping in the solution of the oxymuriate of lime, and boiling in the alkaline ley, are usually repeated four times, when they are found to be sufficiently whitened. The goods are then steeped in a very diluted sour, composed of sulphuric acid, in which they remain for three hours, and some times for a longer period. When they are taken from the sours, they are washed several times in fresh portions of water, to separate any remains of the acid, which would injure the texture of the fibres were they allowed to become dry before this rinsing operation is thoroughly completed. To obviate any risk of this injurious effect, they are immersed in a hot solution composed of four pounds of white soap and one pound of pearl-ashes dissolved in 150 gallons of water. By this scalding process, as it is called, the offensive odour of the oxymuriatic acid preparation is destroyed, and an agreeable softness is communicated to the fabric of the stuffs. Scouring in soap and water, succeeded by repeated washings in cold water, finishes the bleaching process, which is immediately followed by the operation of what is technically denominated *getting up*. After being immersed in hot water, to which a small quantity of soap and a little indigo have been added, they are again scoured with a stronger solution of soap, from which they are completely purified by another washing in cold water. The coarser kinds of goods of this description are steeped in indigo and water alone; but for hosiery of a finer fabric, a very hot solution of soap, beside the addition of the indigo, is employed; and this application, it is found, both improves the colour and communicates a fine gloss.

Dried completely in a stove, by means of artificial heat, the stockings are introduced into the brimstone stove, and exposed to the action of sulphurous acid gas, produced by the combustion of sulphur, without which operation, when they are laid up for some time, they are apt to assume a yellowish shade; but the precaution should be strictly observed of not subjecting them to the vapours of sulphur in a damp state, lest the condensed sulphurous acid should injure the fabric, or, from the unequal portions of moisture, should not act uniformly, and thus produce clouds or spots on different parts of the surface. The finishing operation of dressing is performed after they are taken from the brimstone stove, by slightly damping with water, and drawing each stocking separately on a stocking-leg board, and either smoothing them by the hand with a hot iron, or subjecting them to a strong press.

Chap. III. Of Bleaching the Materials of Paper.

Soon after the powerful effects of muriatic acid were known, the French chemists and manufacturers applied it to the bleaching of the materials of which paper is composed. The processes adopted for this purpose were necessarily modified, according to the nature of the substances, and the impurities which adhered to them.

Old printed and written papers.—In the preparation of printed paper which is again to be worked up, it is boiled for a short time in a caustic solution of soda, after which it is steeped in a solution of soap and water, well washed, and then reduced to a pulp by the usual machinery.

Old written papers which are intended for the same purpose are immersed in a cold solution of sulphuric acid in water, and after being washed are subjected to the operation of the paper-mill. The action of the acidulated water is more powerful when the temperature is moderately increased.

Bleaching rags.—The bleaching of rags for the manufacture of paper is varied according as they are of a natural brown colour, or have been dyed with some artificial colour. In the first case, the rags are opened or separated from each other, ma-

Of Paper.

cerated in water, steeped in a caustic alkaline ley, and then exposed to the action of oxymuriatic acid, more or less concentrated with an alkali. But when the rags have been dyed or printed of different colours, they are first opened or separated, and then immersed in the oxymuriatic acid solution; and if the colour should not be sufficiently discharged by the first immersion, they are passed through water acidulated with sulphuric acid; and if the process should still be incomplete, a second application of the alkaline, oxymuriatic acid, and sulphuric acid solutions, in succession, becomes necessary.

Bleaching the pulp.—A better method of purifying the materials for the manufacture of white paper was fortunately adopted by the same chemist, in the application of the gas to them in the state of pulp or paste.—Much inconvenience arose to the workmen employed, from the offensive and suffocating fumes of the oxymuriatic acid gas, when it was used in the uncombined state. This inconvenience was obviated by adding a certain proportion of potash, so that a solution of oxymuriate of potash was the bleaching liquor; but another difficulty arose from the cohesive nature of the pulp or paste when it was reduced to that state of minute division which rendered it fit for the fabrication of the paper, for it soon subsided in the bath and prevented the uniform action of the liquid upon every part of the mass. This difficulty was removed by subjecting the materials to the bleaching process, after the texture of the rags was so far destroyed as to separate the fibres, without reducing them to that state of minute division which is necessary before they are worked up. By this management of the materials, paper of a pure white was obtained.

Bleaching of printed or written papers.—Should it be required to bleach printed or written papers without destroying the texture of the leaves, in the first case they may be steeped in a caustic solution of soda, either hot or cold, and afterwards in a solution of soap; they are then arranged alternately between cloths, in the way which the paper manufacturer follows, and are then subjected to pressure. If a sufficient degree of whiteness is not effected by the first operation, the process may be repeated a second, and even a third time, when it appears necessary; and after being dried and pressed, the bleached leaves are applied to the same purposes as formerly.

In bleaching old written paper, with the intention of preserving its texture and again applying it to use, the leaves are steeped in a souring liquid prepared with sulphuric acid. The solution may be either hot or cold, as the condition of the written papers may require. They are then immersed in the oxymuriatic acid solution, and after being dried and pressed are again fit for use.

Cleaning prints, &c.—Prints, maps, and books, are cleaned and whitened by the action of oxymuriatic acid gas, and the safest mode of its application is in the liquid form, but particular attention must be paid to the management of the process and the strength of the solution, that the texture of the paper may not be injured. For cleaning an engraving, immersion in the liquid oxymuriatic acid is all that is necessary, and it is allowed to remain for a shorter or longer time according to the strength of the liquor.

When the paper of a bound book is to be whitened, the leaves must be carefully separated from each other, that the action of the acid may be uniform on both sides; and for this purpose the book is opened, and the boards are made to rest on the edge of the vessel, that the leaves only may be immersed in the liquid. At the end of two or three hours the book is removed from the acid, and carefully immersed in pure water, that every part of the paper may come in contact with it, the whole of the remaining acid may be extracted, and the offensive odour may be removed. With this view, it is necessary to renew the water every hour.

But a more effectual method of whitening the leaves is to unsew the book, and to place the separated leaves in cases formed in a leaden tub, with thin slips of wood or glass, so that the leaves when laid flat are separated from each other by very small intervals. The prepared liquid is then gently poured in that the leaves may not be disturbed, and when they are sufficiently whitened the liquid is drawn off by a stop-cock, fresh water is added, and if necessary renewed, to carry off the remains of the acid, and the leaves are dried, pressed, and again bound up. By this process some valuable books have been effectually cleaned.

Spots of oil or animal grease may be removed by means of a weak solution of potash; and similar spots or stains of wax may be effectually extracted by another method. The paper which is stained with grease, wax, oil, or any other fat body, is first to be gently warmed, and as much of the oily matter is to be removed by means of blotting paper as will adhere to it. A small brush dipped in hot essential oil of turpentine is then gently drawn over both sides of the paper, which must still be kept warm; the operation is to be repeated according to the thickness of the paper and the quantity of oily matter which it has imbibed. The whiteness of the paper may be restored by dipping another brush in highly rectified spirit of wine, and drawing it over the stained spot, and more especially round its edges. By the cautious use of these means, the spot entirely disappears, and the paper recovers its original whiteness.

Chap. IV. Of Bleaching Bees-Wax.

Of Bees-wax

The time of bleaching bees-wax has been also greatly abridged by the discovery of the new method. It was formerly the practice to expose the wax in the form of thin cakes to the action of the air and weather; but the great saving of time renders the use of the oxymuriatic acid preferable.

The simple acid is employed in the bleaching of wax, and the effect is most powerful when it is applied in the gaseous form. A pneumatic tub, well secured with a close cover, to prevent the escape of the gas, is employed for this purpose. This vessel is filled with water, and the wax, which is to be shred into thin pieces, being introduced, a current of the oxymuriatic acid gas is passed through the water, which is to be kept in constant agitation by means of the usual apparatus. This operation is continued for an hour or two, at the end of which time the wax is generally found sufficiently whitened, and being removed from the water it is melted down and formed into cakes.

Chap. V. Of Bleaching Wool.

As wool is an animal production, it contains a large proportion of those elements which enter into the composition of animal matters. The affinity which exists between the different constituents of animal substances, is more feeble than the affinity of the elements of vegetables, so that they are more liable to decomposition by chemical agents; and hence alkalies and acids have a powerful action on animal productions.

Chemical analysis shews, that wool contains carbonate of ammonia and a considerable proportion of oily matter. It is little changed by exposure to the air; boiling water scarcely produces any action upon it; a strong heat reduces it to a state of fusion. Acids have little effect; but the alkalies in their caustic state entirely decompose it, and form soap.

In bleaching wool, it is subjected to two operations; the first is scouring, and the second is sulphuring or whitening.

Sect. I. *Of Scouring Wool.*

By the operation of scouring, the oily matter which is combined with the wool is separated, which is necessary before it can be subjected to the processes by which it is whitened. For this purpose, a mixture of five parts of river or soft water, with one part of stale chamber-ley, is prepared, by boiling for a short time. As the latter ingredient contains a considerable portion of ammonia, the mixture is to be regarded as an ammoniacal solution, the effects of which are less active than those of the other alkalies.

After steeping the wool for a short time in this solution, it is stirred about for a quarter of an hour, or twenty minutes, that the whole of the greasy matter may come in contact with the solution, and be removed. The wool, placed in a basket, is allowed to drain; and the liquid which passes off is returned to the steeping vessel. The wool is then perfectly washed in a stream of pure water, till the water passes off quite clear. The same processes of steeping and washing are repeated until the wool has acquired that degree of whiteness which it is capable of receiving from this operation.

In steeping fresh quantities of wool, as the power of the bath is weakened, it is necessary to add a fresh quantity of the ley. The temperature also may be increased to render it more effectual; but it is necessary, at the same time, to observe caution in this management, for too high a temperature renders the greasy matter difficult of solution, and the wool becomes harsh when too much of the ley is employed. But the openness, elasticity, softness, and whiteness of the wool, afford the proper tests of the process being properly conducted. The loss of weight which it sustains in scouring is sometimes more than fifty per cent.; but the amount of this loss varies according to the nature of the wool, and the impurities with which it is contaminated.

For finer kinds of wool, a more expensive process is followed: A bath is prepared of black soap dissolved in boiling water; and after the wool has been washed in this bath, it is wrung out, and exposed to the air or sunshine to dry. A second scouring is necessary to clear it entirely of the oily matter, before it is fit for combing; and after it has undergone this operation, if a very pure white be required, two or three additional washings are sometimes necessary.

Sect. II. *Of Sulphuring Woollen Stuffs.*

For many purposes a brighter white is requisite than can be obtained by the process of scouring. This is effected by exposing it to the action of sulphurous acid. The operation of sulphuring is generally performed on the woollen stuff when it is in the state of cloth; and it is conducted in the following manner.

The pieces of cloth are arranged on poles in a close apartment, and a quantity of sulphur, in broad flat vessels, is set on fire, and burns gradually in the chamber, which is made so tight that none of the vapour can escape. The fumes of the sulphur, which is now in the state of sulphurous acid gas, penetrate the pores of the cloth, and completely destroy the colouring matter. This operation requires from six to twenty-four hours; and by passing the cloth through a bath in which a small portion of soap has been dissolved, the roughness and harshness which are left by the action of the vapours of the sulphur are removed.

But on examining woollen stuffs whitened in this way, it was found that the effect of the vapour was confined to the surface of the goods. To produce a more perfect and more permanent whiteness, the sulphurous acid dissolved in water is recommended and employed for this purpose. The apparatus which is used in the preparation of liquid sulphurous acid, is similar in its construction to that which is employed in the production of oxymuriatic acid. The most economical method of decomposing the sulphuric acid, for the purpose of obtaining sulphurous acid gas, is to take a quantity of chopped straw, saw-dust, or some similar substance, which being introduced into a matrass, sulphuric acid is poured upon it, and the vapour which is evolved is conducted into a series of vessels with water in the apparatus alluded to. When the water is sufficiently saturated with the gas, it is drawn off into the vessel in which the stuffs are to be immersed. When woollen stuffs are bleached by this method, they are first scoured in a weak alkaline ley, in which the proportion of potash is not more than one pound to fifty pounds of wool, and the temperature of the bath is raised to about 100° Fahrenheit. After scouring, the goods are washed in a warm solution of soap; and when a high degree of whiteness is wished for, a second, and sometimes a third washing in the soapy solution is required before the process of sulphuring is employed. The stuffs are then passed through the bath impregnated with sulphurous acid, and the operation is continued, by means of a winch, till the proper degree of whiteness is obtained. This is usu-

Of Silk.

ally effected in two or three hours at a single immersion. The stuffs are then drained on a table, which is closely covered up with a cloth, to prevent the action of the air on the sulphurous acid, which, by the change produced on it, might injure them; they are then well washed in running water, and some times steeped in water in which Spanish whitening is diffused, with the addition of a small quantity of indigo or Prussian blue, to improve the whiteness.

Chap. VI. Of Bleaching Silk.

Silk is an animal production, which is prepared by the silk worm, for its cover, in that state which precedes its appearance as a perfect insect. It is then said to be in its raw state, and is covered with a yellow varnish, or gum, which renders it rough and hard, and impairs its lustre. Water, even at the boiling temperature, produces no change on silk, and alcohol has no effect upon it; but alkaline leys, of sufficient strength, dissolve it, as well as the yellow varnish with which it is covered.

Sect. I. *Of Scouring Silk.*

In conducting the process of scouring silk, thirty pounds of soap are dissolved in water for every hundred pounds of the silk. To complete the solution the water is kept some time at the boiling temperature; but, before the immersion of the silk, the temperature is reduced to 90° of Fahrenheit; and it is kept at the same degree during the whole of the process. The silks, suspended on rods or frames, are immersed in the liquid, and allowed to remain till the gum is entirely dissolved; and that every part of the stuff may be exposed to the action of the bath, their position should be occasionally changed. They are then wrung out and well shaken, put into coarse linen bags, in separate parcels of twenty or thirty pounds each, and again steeped in a fresh bath, prepared with a small proportion of soap. They are boiled in this bath for two or three hours, and often stirred up with a stick, to prevent the bags from adhering to the bottom of the boiler. The silk is then wrung out and well washed in a stream of water; and if the bleaching be not uniformly perfect, immersion in the bath must be repeated.

Steeping in the lukewarm bath is not required for silks which are to be dyed; the boiling is considered sufficient; but a larger proportion of soap is employed according to the fineness of the colour. For common colours, thirty pounds of soap for every hundred pounds of silk are found to answer; but for the poppy, cherry-red, and some other colours, fifty pounds of soap to every hundred pounds of silk are necessary.

Bleaching by steam.—In the processes of scouring, which have been just described, the silk stuffs are apt to suffer in their texture. To obviate this inconvenience it has been proposed to bleach them by the action of steam. The apparatus for bleaching cotton by the same process is employed. The boiler is filled with a weak solution of caustic soda; the raw silk is placed on the frames, and it is exposed to the steam of the liquid, which is raised by boiling for ten or twelve hours. By the action of this vapour,

2

the temperature of which is about 250° Fahren. the gum of the silk is removed, and the stuff itself is whitened. After washing with warm water, and being well wrung, the silk is again placed on the frames of the apparatus, and subjected to a second steaming. The washing in a large quantity of water is repeated; and, to give softness to the stuff, rinsing in water, slightly impregnated with soap, is employed.

Sect. II. *Bleaching Process.*

Although silk stuffs are considerably whitened by the different operations of scouring now detailed, a brighter lustre is required for most purposes. To produce the most perfect whiteness they are exposed to the action of sulphurous acid, according to the method which is practised in bleaching wool; and in this case also the whitening process, by means of this acid, is conducted by using it either in the state of gas or in the liquid form, and the same apparatus answers the purpose.

Sect. III. *Of Bleaching with Alcohol.*

The method of bleaching silk, without destroying the gum, was long ago proposed by the French. In this process, spirit of wine and muriatic acid are employed. The bleaching liquor is prepared by mixing a pound of alcohol with an ounce of muriatic acid; and the quantity to be prepared in the same proportions should be sufficient to float the silk. The stuff to be bleached is introduced into a glass vessel along with the liquid, and, being closely covered up, is exposed for twelve hours to the sun, or to a corresponding temperature in the shade for double the length of that time. The silk is then taken out, pressed, and again steeped in a fresh portion of the same liquid, and for the same length of time. It is then taken out, pressed, and washed for a few minutes in pure spirit of wine. Placed in a third vessel with pure alcohol, it is kept for twenty-four hours in the sun, or thirty-six hours in the shade, and the alcohol, as it evaporates, is renewed. The silk is then taken out, pressed, and washed two or three times in fresh portions of pure water; and, last of all, it is dried on a frame, upon which it ought to be strongly stretched to prevent its curling.

But as this is obviously an expensive process, in consequence of the high price of the materials, another method has been proposed, by which the alcohol employed may be recovered. This method was proposed by Baumé, a French chemist. In gauzes and some other fabrics of silk, it is necessary to preserve the natural elasticity and stiffness, and at the same time give a proper degree of whiteness. This is effected by destroying the yellow colour of the silk, and at the same time retaining the gum.

By the usual management of the balls, or cocoons of silk, as they are produced by the insect, they are introduced into an oven, and exposed to the temperature of about 158° Fahrenheit, for two hours, for the purpose of destroying the insect before it has time to eat its way through the ball. By this process of baking it was observed, that it was more difficult to wind off the silk, which besides becomes hard, inferior in quality, smaller in quantity, and less susceptible of a fine lustre. To

Of Silk.

obviate these disadvantages, M. Baumé thought of destroying the insect by means of spirit of wine. The cocoons are arranged in a wooden box, in a stratum of six inches deep, and about half a pint of spirit of wine is sprinkled upon them; they are then mixed by the hand, another stratum is placed over the first, which is also sprinkled uniformly with the same liquid. Proceeding in this way, the box is filled, covered up, and allowed to remain for twenty-four hours, during which the heat is increased, and the spirituous vapour destroys the insects, after which the balls are spread out to dry. The spirit of wine which is preserved in glass vessels, or in those of pure tin, or tinned copper, only should be employed in this process. Leaden vessels should never be used, and wooden vessels are apt to tinge the spirit, which communicates a colour to the silk that is not easily removed in the bleaching process.

The cost of the spirit of wine employed in this process, it is observed, is fully compensated by the saving of labour and fuel, and by the greater produce of silk of a superior quality. It possesses, besides, another advantage, that the cocoons in which the insects have perished before being exposed to the action of the spirit of wine, are more easily distinguished, and as they afford a much worse silk, they ought to be separated from the rest.

The cocoons are immersed in water nearly at the boiling temperature, and the silk is then wound off upon a reel. The water employed in silk manufactories, it is properly observed, should be of the purest quality; and the alum which is used in some countries ought to be rejected; for no saline substance contributes any thing to the beauty or colour of the silk, and in many cases it may prove injurious. After the silk is wound upon the reel, and the threads separated, which are apt to stick together at the four places where they come in contact with the arms, which is done by soaking it in warm water for about two hours, and opening the bands upon a pin, and lightly rubbing the coherent parts, it is dried, loosely folded in its original form, and is then ready for the bleaching process.

Method of bleaching.—A stone-ware vessel, of a conical form, of twelve gallons capacity, and having a large opening at one end, with a smaller one of about an inch in diameter at the other end, is employed for the purpose of bleaching silk according to this method. This vessel must be of such a nature as shall not be acted upon by the liquids, and must be entirely free from pores, that no part of the inclosed liquor shall be lost by leakage. To remove the asperities on the inner surface, which might entangle and break the threads, it is to be rubbed and smoothed with pumice-stone; and a cover, of the same material as the jar itself, is carefully fitted by grinding. When this vessel is employed it is inverted; and the smaller aperture, which is then lowest, is furnished with a cork, through which a glass tube, about a quarter of an inch in diameter, passes, for the purpose of drawing off the liquid when the process is completed. A perforated false bottom is introduced within the jar to prevent the tube from being obstructed. The jar is supported by a wooden frame, immediately under which is placed a cask to receive the liquid as it passes off through the glass tube in the several periods of the bleaching operation; and the apparatus is so contrived that the liquor is conveyed through glass tubes to the receiving vessel below, that it may not be exposed to the air, by which part would be dissipated by evaporation.

The proportions of the mixture employed in bleaching silk by this method are, twelve pounds of spirit of wine to three ounces of pure muriatic acid. The silk being disposed in the stone vessel, the liquid is poured upon it, and allowed to remain for twenty-four hours, when it is run off, and clean spirit of wine is poured upon the silk, and repeatedly drawn off till it passes colourless. The silk being allowed to drain, is ready for a second infusion, with a fresh portion of the liquid, composed of the same proportions of spirit and acid; and it remains in this infusion for one, two, or three days, and even a longer period, till the silk become perfectly white. This mixture being drawn off, clean spirit is sprinkled upon the silk, while it is at the same time pressed down with the hand; and when the spirit comes off colourless, an infusion of spirit, without acid, in the same proportion as in the two first infusions, is poured upon the silk; and after remaining for twenty-four hours, the silk is left to drain, when it is sprinkled with a small quantity of pure water, and this is continued till the water passes off colourless and tasteless. To separate the remaining portions of the muriatic acid, the silk is loosely put into a coarse woollen bag, which is still farther secured by means of another bag, and placed in a basket, which is left for five or six hours in a stream of water, or, where this is wanting, water may be pumped upon a cloth cover, and allowed to pass through the stone-jar for the same time, or until no indications of acid appear in the liquid as it drains off.

Recovery of the alcohol.—The expensive nature of the materials employed in bleaching silk by this process, soon suggested the means of recovering or restoring it to a state of purity; and for this purpose two methods have been proposed. In the first method the acid is saturated with potash, to allow the distillation to be performed in a copper vessel, and is lost; and in the second the distillation is conducted with a silver or glass apparatus, which is not acted upon by the acid, and in this way the acid itself is saved.

The first method is considered the most economical in a manufactory. A solution of potash is added to the acid spirit, which is agitated to promote the saturation, which is ascertained by the fluid no longer reddening the tincture of turnsole, or any other test of acids. When the potash is added, strong effervescence, with the evolution of carbonic acid, takes place. The distillation is then to be carried on in the apparatus of copper, and the alcohol obtained is received and preserved in proper vessels. If too much of the alkali shall have been added, the liquor remaining after the distillation is completed may be employed for the saturation of another portion of acidulated spirit. In the view of still greater economy in the process for the recovery of the alcohol, chalk and quicklime were employed as substitutes for the potash. But it was found that the calcareous earth united very slowly or imperfectly with the acid; for when the fluid was very largely diluted with water, the saturation was scarcely completed in five or six weeks.

By the second process, when the distillation is conducted without alkali, glass retorts are charged with the acidulated spirit, and are arranged on the sand-bath in the gallery of a furnace. The first product has little acidity, but the portions which afterwards come off become gradually more acid, and must be preserved in glass or stone-ware vessels. The first liquor which comes over is reddish and turbid. This is rejected, and the receivers are changed. The succeeding product is the colourless muriatic acid, which has a peculiar aromatic odour, somewhat resembling the buds of poplar. The resin of the silk, decomposed by the acid, remains in the retort; the muriatic acid is obtained of diminished strength, but it is in a state of considerable purity, and, if necessary, may be concentrated by the usual method.

When this new process of bleaching silk was announced, numerous manufactories were immediately established in France; but not being aware of the importance of the materials employed being perfectly pure, the proprietors of some of them were subjected to considerable disappointment and loss. The muriatic acid of commerce was found unfit for the purpose, because it rarely happens that the sulphuric acid which is used for disengaging the muriatic acid from common salt is entirely free from nitric acid; so that the purification of the sulphuric acid becomes a necessary preliminary step in the process.

Chap. VII. Miscellaneous Operations.

In extensive bleaching establishments, where large quantities of materials, some of which are expensive, are employed, it becomes a matter of no small importance to be able to recover such as may be applied to useful purposes. In the present chapter, some of the methods which have been resorted to for the separation and purification of the valuable substances which remain after the distillation of oxymuriatic acid, or the preparation of its compounds, may be briefly noticed; to which it may be useful to add a short account of the methods of scouring and cleansing various stuffs, and of removing accidental spots or stains with which they are contaminated. Such extemporaneous processes may be considered as rather connected with domestic purposes than belonging to large manufactories. The principles are the same, but their application is less systematically conducted.

Sect. I. *Residuum of the distillation of Oxymuriatic Acid.*

The substances which remain after the distillation of oxymuriatic acid, have been very generally rejected as useless. As may be supposed, from the complicated action of the ingredients employed, various compounds remain after the process is completed. These substances are chiefly a portion of oxide of manganese which has been added in excess, some sulphate of manganese, and a large quantity of Glauber's salt, or sulphate of soda.

It has been suggested, that the whole mixture might be successfully employed as a glazing for the coarser kinds of earthen ware, to which it communicates a dark brown colour, from the metallic matter which it contains. It has been suggested also that the waste residuum from the preparation of oxymuriatic salts would be a useful application in improving and fertilizing the soil. But experiments, it may be hinted, are still wanting to ascertain its effects in this way.

Sulphate of soda.—To extract the soda in a pure state from this mixture, provided the process were not expensive, would be attended with great advantage; but even the separation of the sulphate of soda, a less difficult operation, would be followed with considerable profit. To accomplish the latter object, the separation of the sulphate of soda, solution and crystallization are the only requisite processes. For this purpose an extensive establishment was begun in Lancashire, which furnishes an immense quantity of these materials, and it succeeded in the production of excellent Glauber's salt; but the prohibition by government of the sale of the residuum put a stop to the operations; so that the bleacher must purify the waste materials for himself, or throw them aside as useless.

Soda extracted.—The decomposition of the sulphate of soda, for the purpose of obtaining the alkali in a separate state, is an object of still greater importance; and with this view attempts have been made by chemical manufacturers. In one of the methods which has been followed for the decomposition of Glauber's salt, one part of charcoal powder, and nine parts of sulphate of soda being well mixed together, were exposed to the heat of a reverberatory furnace; and when the sulphuret obtained by the decomposition of the acid was in a state of combustion, from three to five parts of old iron, reduced to very small pieces, were added. The fusion of the whole gave a black mixture, composed of iron, soda, and sulphate of iron, which being dissolved in water, and filtered through a basket filled with lime, the clear liquid was evaporated to dryness, and the saline substance was calcined in a reverberatory furnace. The farther purification of the soda thus obtained is completed by a repetition of the processes of solution and crystallization.

The decomposition of the sulphate of soda has been attempted by means of carbonate of lime, for the purpose of neutralizing the alkali by saturation with carbonic acid at a very high temperature. Two parts of sulphate of soda, from which the water of crystallization has been driven off, two parts of chalk reduced to fine powder, and one part of charcoal dust, are well mixed together, and subjected to a white heat in a reverberatory furnace; when the mixture is in a state of fusion, it is constantly stirred till the whole of the sulphur is consumed and the flame ceases to appear. The soda is obtained in a state of purity by repeated lixiviation and evaporation in the usual way. But by whatever process the decomposition of this salt is effected, the extraction and recovery of the soda would render the expense of oxymuriatic acid preparations comparatively trifling to the bleacher, and may therefore be considered as an object of considerable importance.

SECT. II. *Of Cleansing or Scouring different Stuffs.*

As coloured stuffs are often contaminated with spots or stains, a double object must be kept in view in purifying or scouring them. On this subject M. Chaptal has thrown out some excellent hints, which, with the aid of a little chemical knowledge, may be highly useful, not only for domestic purposes, but to the manufacturer on a larger scale. In conducting these processes properly, he observes, it is necessary to be acquainted with the nature of the substances which produce stains,--of those by which stains are removed,—of the effects of these re-agents on the colours, and on the cloth itself,—and of the means of restoring a changed or faded spot. Stains or spots on cloths are produced by oily or greasy substances, acids, alkalies, perspired matter, fruits, &c. Some of these, as the oily or greasy stains, are easily distinguished by their appearance, but the effects of others are of a more complicated nature.

Acids communicate a red colour to black, fawn, and violet-coloured cloth, and to the different shades obtained from archil weed, iron, astringents, and to all the blues, except indigo and Prussian blue. By the action of the acids yellows become paler, except the yellow of anatto, which is changed into orange.

The reds which are produced by Brasil wood, logwood, and cochineal, are converted into violet by the alkalies. The greens on woollen cloth are rendered yellowish by their action; yellow becomes brownish, and the yellow from anatto is changed to aurora. The effects of perspired matter on different cloths are similar to those of the alkalies.

The removal of the stains or spots produced by simple bodies on stuffs, is easy and certain. Oily or greasy matters are removed by alkalies, soaps, the yolk of eggs, or some of the fat or absorbent earths; the oxides of iron by the oxalic or some of the mineral acids greatly diluted; stains from acids are destroyed by the action of alkalies; and spots from alkalies disappear by the effect of acids. Fruit stains are removed by sulphurous acid, and still more effectually by the proper application of oxymuriatic acid. But when the stains are of a complicated nature, different methods must be employed in succession for their removal, as, for instance, when any oily matter combined with iron forms a spot on cloth, the greasy matter must first be separated, before the re-agents, which dissolve the iron, can be applied.

Revival of the colours.—It rarely happens that the colours of stuffs which are subjected to the action of the different re-agents employed in the operation of scouring or cleansing, are not in some degree changed or diminished in their brilliancy. Here, therefore, a knowledge of the art of dyeing becomes necessary for the purpose of modifying the means of cleansing stuffs, and at the same time of retaining the colours, or at least of being able to revive those which are injured, and to restore their former intensity. The nature of the colour and of the ingredients by which it was produced, it is obvious, must direct to the proper means for obtaining these ends. If, for example, an alkali be employed to destroy an acid stain on stuffs of a brown, violet, blue, or poppy colour, the yellow spot which remains, vanishes by the application of a solution of tin; the colour of brown stuffs which have been galled, is restored by a solution of sulphate of iron; acids revive the intensity of yellow colours which have been rendered dusky, or brown, by alkalies; acids redden blacks which are produced by logwood; but by the action of alkalies the red spots are converted to yellow, and by means of astringents the black colour is restored. The blue colour of cotton or wool which has been changed, may be successfully revived by a solution of one part of indigo in four parts of sulphuric acid, diluted with water; and the brilliancy of scarlet is restored by means of cochineal and a solution of muriate of tin.

The selection of re-agents requires attention; vegetable acids, as less liable to produce injury, are to be preferred, but the sulphurous acid may be employed for removing fruit stains; for neither the blue of silk, nor the colour produced by astringents, nor the yellow of cotton, is changed by its action. The stains produced by acids are more successfully removed by ammonia than by means of the fixed alkalies; and when it is applied in the state of vapour the action is speedy and effectual, while the colour is rarely altered.

Stains of a complicated nature.—When the spots or stains on stuffs seem to have been produced by compound substances, and when a simple re-agent has no perceptible effect in removing them, compound matters are successfully employed. The following composition has been found very efficacious in such cases: To a solution of white soap in alcohol, add the yolks of four or five eggs, a portion of the essence of turpentine, and some fuller's earth. Mix the whole intimately, and form the mass into balls, which are to be rubbed on the stained spot, moistened with a little water. After washing the spot with clean water the stain generally disappears.

But as washing destroys the lustre of stuffs of a delicate fabric, it may be fully restored by drawing over the washed place, in the direction of the pile, a brush, moistened with water in which a little gum has been dissolved. A sheet of paper, or a piece of cloth, is laid on the stuff, and a considerable pressure is applied till it is quite dry.

Another process.—The following simple preparation is recommended as a useful application in cleaning silk, woollen, and cotton stuffs, without injury to the colour or texture of the cloth: Take a quantity of raw potatoes, and grate them down to a fine pulp over a vessel of clean water. Pass the liquid matter through a coarse sieve into another vessel of water, and let the mixture remain at rest till the fine white particles of the potatoes have subsided. Pour off the clear liquor, and preserve it in bottles for use. The stuff to be cleaned is spread upon a linen cloth on a table, and a clean sponge, dipped in the liquid, is drawn over the soiled parts, and this operation is continued till the stains disappear. The stuff is then to be washed several times in clean water, to remove the loosened impurities, and it is smoothed and dried in the manner directed above.

Two potatoes of moderate size are sufficient for an English pint of water in the preparation of this liquid. The white fecula which subsides may be used as starch or hair-powder; and the coarse pulp which remains in the sieve may be employed in cleansing worsted curtains, tapestry, carpets, and other coarse goods. The application of the liquid obtained in this way has been extended to the purpose of cleaning oil paintings, soiled furniture, and painted wainscoats.

Sect. III. *Extemporaneous Processes.*

The knowledge of chemistry directs to a variety of simple processes for removing spots or stains from clothes, books, furniture, &c.; and as many of the reagents employed for these purposes can be readily procured, and are of easy application, it may be useful to enumerate some of the processes which are most efficacious in removing those spots or stains, or other impurities which are of most frequent occurrence.

Spots of grease, &c.—Spots of grease, which have been recently produced on cloth or paper, into the pores of which the oily matter sinks and spreads, may be often entirely removed by laying the piece of cloth or paper between two folds of blotting paper and applying a hot iron. The grease is melted by the heat, and is absorbed by the paper; and if the whole is not removed by the first application, a clean part of the paper is placed on the contaminated spot, and the operation is again repeated. In some cases a weak alkaline solution may answer the purpose; or where there is any risk of the colours of the stuffs being injured, either by heat or by the action of the alkali, heated spirits of turpentine may be successfully employed. Stains of white wax may be also removed by spirits of turpentine.

Oil paint.—Recent spots of paint are often very easily removed by washing immediately with soap and water. But such as have been allowed to dry, and to remain for any length of time, may be effectually extracted by spirits of turpentine.

Spots of tar or pitch.—The clothes of persons who are on ship-board are apt to contract spots of tar by coming in contact with ropes or other parts of the vessel; and goods which are conveyed by water-carriage are sometimes contaminated with similar stains. Spirit of wine has the property of dissolving tar completely. The spot may therefore be removed by immersion in this liquid. Spots of tar may be also extracted by rubbing the part with olive oil; and in some cases, where the spot has been recently contracted, it may be removed by a hot solution of soap and water.

Ink stains.—The stains of common writing ink on cloth, paper, or wood, may be extracted by means of almost all the acids; but as the vegetable acids can be employed with less danger to the texture of the substance to be purified, they are to be preferred. All that is necessary is to moisten the spot with a solution of oxalic, citric, or tartaric acids in water, and the application is to be repeated till the spot disappear. As the acids produce no effect on printing ink, they may be effectually employed in discharging written characters from books, without injury to the text. But similar stains are effectually removed, and, under proper management, with equal safety, by very diluted solutions of sulphuric or muriatic acids. The vegetable acids which are employed for this purpose are sold in the shops under the name of salt of sorrel and essence of lemons.

Iron moulds.—Stains of iron are produced on cloth either by coming in contact with iron rust or in consequence of the cloth being washed with soap after receiving ink stains. When such stains have not been of long duration, they are easily removed by some of the vegetable acids already alluded to, or by diluted muriatic acid. But when they have continued long in the cloth, the extraction of such stains is a difficult operation, because the changes which they undergo by repeated moistening with water, and exposure to the air, render them insoluble in acids. The previous application of an alkaline sulphuret, and the succeeding washing of the cloth with water, facilitate the action of the acid and the removal of the stain.

Stains of grease and iron.—Clothes which accidentally come in contact with those parts of machinery which are oiled or greased for the purpose of diminishing friction, contract complicated stains, which must be removed by different re-agents. The greasy or oily matter is first to be extracted by the methods already recommended, after which the iron may be removed by the use of some of the vegetable acids.

Spots of wine, &c.—Stains of wine, cyder, and most kinds of fruit, are, in general, easily effaced by means of oxymuriatic acid; a few drops of the liquid used on a fresh stain causes it almost instantly to disappear. Some fruits, such as plumbs, require the process to be repeated. A very easy method of applying the oxymuriatic acid in the state of gas, is to take a table-spoonful of muriatic acid and to pour it on a tea-spoonful of manganese in powder in a teacup, to place the cup in a larger vessel filled with hot water, and exposing the stained spot, moistened with water, to the fumes which arise from the mixture. This operation is to be performed under a chimney, that the offensive vapour may be carried off.

Such stains may also be effaced by means of sulphurous acid, either in the liquid form or in the state of gas; and a very easy and economical method of employing the sulphurous acid gas is to moisten the stained part of the cloth with water, and to expose it to the fumes evolved by burning two or three brimstone matches. Stains on silk may be removed by a similar process, or by an aqueous solution of the same acid.

The reader who wishes to be more fully informed on the subject of bleaching, may consult the works of Berthollet, Pajot de Charmes, and O'Reilly, Chaptal's Chemistry applied to the Arts, Vol. III. and Parkes' Chemical Essays, Vol. IV.

INDEX.

BLEAK, a species of Cyprinus. See ICHTHYOLOGY.

BLECHNUM, a genus of plants belonging to the order Filices and class Cryptogamia.

BLEEDING, the discharge of blood, either artificially produced, or in consequence of injury or disease. See MEDICINE and SURGERY.

BLEKINGEN, a province of Sweden, which stretches along the Baltic nearly seven miles, is about 25 miles in breadth, and is covered in many places with thick forests of oak and pine trees. Carlscrona, which is the capital, Carlsham and Solvitsberg, are the principal towns. The soil of this province is not very susceptible of cultivation; hunting and fishing are the chief occupations of the inhabitants; and their export trade consists of tallow, hides, leather, tar, and timber.

BLEMMYES, a rude people of Ethiopia, who are represented as being deformed in their persons, and whom the fabulous accounts of the ancients described as being without heads, and having their mouths and eyes placed in the breast. But it appears, from authentic history, that this people joined the Egyptians in their opposition to the Romans under Dioclesian, in the third century.

BLENDE, an ore of zinc. See MINERALOGY.

BLENHEIM, a village in the circle of Suabia in Germany, which has become memorable in history in consequence of the total defeat of the French and Bavarians, and the splendid victory of the British and their allies in its vicinity, on the 13th of August 1704. The French army, composed of 60,000 men, was led by marshall Tallard and the duke of Bavaria, two of the most celebrated generals of the age. The British army and the allies amounted to 55,000 men, under the command of prince Eugene and the duke of Marlborough. The battle commenced about nine in the morning, and the cannonading continued for more than three hours. The troops then advanced to the attack, the right wing under the direction of prince Eugene, and the left headed by the duke of Marlborough, and in a short time obtained a most decisive victory. Marshal Tallard, and many other officers of rank, were taken prisoners; 10,000 French and Bavarians were left dead on the field; the greater part of the cavalry perished in attempting to cross the Danube; 13,000 men were made prisoners; and 100 pieces of cannon, with 24 mortars, 129 colours, 171 standards, beside a considerable treasure, fell into the hands of the victorious army, of whom 4500 men were killed, and about 8000 were wounded or taken prisoners. Blenheim is twenty-four miles from Augsburg, eight miles from Donnawert, and two miles from Hochstet, which latter sometimes gives name to this memorable battle.

As a reward for his services, the manor of Woodstock was appropriated to the duke of Marlborough and his heirs, and a grant of L.500,000 was made by Parliament to erect the princely mansion which received the name of Blenheim house, in commemoration of his victory and triumph. Even the tenure by which the manor is held, refers to the same splendid event; for a flag embroidered with *fleurs-de-lis*, is to be annually presented at the castle of Windsor, on the day on which the battle of Blenheim was fought.

BLENNIUS, the Blenny, a genus of fishes belonging to the order Jugulares. See ICHTHYOLOGY.

BLIGHT, an affection of plants, which has sometimes been ascribed to disease, and sometimes to the work of insects, and is particularly incident to grain. See *Wheat*, under AGRICULTURE.

BLIND, an appellation applied to those who are deprived of the sense of sight. For an account of the methods which have been invented and practised for the instruction of those who labour under this unfortunate privation, see EDUCATION.

BLITUM, *Blite, or strawberry spinage*, a genus of plants belonging to the Monandria class.

BLOCK, a frame of wood with one or more pulleys, employed in the management of the rigging of ships, as well as for other purposes, to increase the mechanical powers. For an account of the different kinds of blocks, and of the ingenious machinery which is employed in making them, see SHIP-BUILDING.

BLOCKADE, a term in military affairs, which is applied to a place from which all supplies of men and provisions are cut off by the vigilance of a besieging army, for the purpose of compelling the besieged to surrender without any direct assault; and hence to raise a blockade, is to force the besieging troops to retire from their posts.

BLOIS, a town of the department of Loire and Cher in France, which is finely situated, partly on an eminence, and partly on a plain on the banks of the Loire. The castle, the cathedral, the Jesuits college, the gates of the city, and the bridge over the river, some of which are magnificent edifices, are the principal buildings. The supply of water is furnished by an aquæduct, supposed to be of Roman construction, and from a large reservoir near the walls it is distributed to different fountains. The population exceeds 13,000. The manufactures of serges, gloves, hats, stockings, and some hardware, are considerable; and the principal trade consists of brandy and wines, which are conveyed by water-carriage to Orleans, Paris, and other places of France.

BLOOD, the fluid which circulates through the vessels in the bodies of animals. For an account of which, see ANATOMY.

BLOOD-STONE, a mineral substance, belonging to the Siliceous genus. See MINERALOGY.

BLOSSOM, the flower of a plant, which contributes to the ripening and protection of the seed of the embryo fruit.

BLOW-PIPE, an instrument employed in chemistry and mineralogy, for producing a very intense heat by the flame of a candle or lamp, and thus by an easy process making experiments on small portions of substances, to asertain some of their properties and habitudes. See MINERALOGY.

BLOWING-MACHINE, is an apparatus for forcing air into a furnace with great velocity, for the purpose of increasing the power of combustion, and the rapidity of smelting operations. See FURNACE.

BLUE, one of the seven colours into which a pencil of rays of light is divided by the intervention of a glass prism. See OPTICS.

BOA, a genus of serpents, some species of which acquire the largest size of this tribe of animals.

BOADICEA, a British queen, who is celebrated in history for her brave resistance to the Roman arms. Her husband, the king of the Iceni, bequeathed to his two daughters, and to the emperor Nero, the whole of his dominions and treasures, in the hope of securing to his family and people the friendship and protection of the Roman governor. But, on his death, the Romans seized the whole; and the opposition and remonstrances of Boadicea to their unjust proceedings brought upon her a most barbarous treatment. She herself was subjected to scourging, a punishment inflicted only on slaves, and her daughters were violated. The irritated Britons flew to arms, and, with Boadicea at their head, were determined to shake off the Roman yoke.

To oppose the vigorous efforts of the Britons, the Romans were obliged to collect their scattered forces, and, after a bloody battle, in which success long remained doubtful, victory at last declared in their favour. Dreading the consequences of falling into the hands of her enemies, from whom neither mercy nor generosity was expected, the unfortunate Boadicea destroyed herself with poison.

BOARD signifies a piece of timber which is sawn into thin pieces for various purposes; the same term is applied to a table or bench on which artisans perform their work, as, a work-*board*, shop-*board*; it denotes also a frame on which certain games are played, as, a draft-*board*, a chess-*board*; and likewise an office where public business is transacted, as, the *board* of works, the *board* of ordnance.

Board is also a naval term, which signifies to go into a ship, as when it is said to go on board.

BOARDING is a term in naval tactics, when the crew of one ship, determined speedily to finish the combat, go on board the ship of the enemy, and attack them with small arms.

BOAT, a small open vessel, which is employed in short voyages, and is conducted on the water either by rowing or sailing. Boats are constructed of different forms and sizes according to the purposes for which they are destined. See SHIP-BUILDING.

BOAT, LIFE, a boat of a particular construction, which is well calculated for resisting the violence of a stormy sea, and is thus fitted to afford relief to stranded vessels, and to save the lives of the unfortunate mariners; and from this circumstance it derives the name of life-boat. See SHIP-BUILDING.

BOAT-BILL, a species of bird. See *Cancroma*, under ORNITHOLOGY.

BOATSWAIN, a naval officer, to whose charge is committed the management of the boats, sails, rigging, &c. It is also the business of the boatswain to summon the crew of the ship to their duty, and to attend to the change of the several watches.

BOCCACE, or BOCCACIO, JOHN, a celebrated Italian writer, was the son of a peasant in Tuscany, and was born in 1313. Placed by his father under the tuition of a merchant at Florence, for the purpose of being instructed in the knowledge of commercial affairs, to which his future life was destined, he was fortunate at first in securing, by his industry and fidelity, the approbation of his master; but the charms of poetry, which captivated his fancy, rendered the dull routine of trade irksome; he grew careless in business, and, after six years service, he was dismissed for negligence. The study of law, to which he afterwards directed his attention, was not more congenial to his taste; and having relinquished every plan of life that was suggested or urged by his friends for the pleasures of poetry, he attached himself to Petrarch, and, while he enjoyed his friendship and instruction, his exhausted finances obliged him to share in the bounty of that immortal bard. Boccacio was initiated in Greek literature by a learned native of Thessalonica, who visited Italy; the fame of his attainments spread abroad; and the Florentine republic conferred on him some honorary marks of distinction. Employed in the management of important public affairs, he was charged with the mission of soliciting the return of Petrarch, whom the violence of faction had driven from Florence. But the literary friends preferred quiet and retirement, in security, to honours and emoluments in the midst of bustle and danger.

Having spent several years at the courts of Italy and Sicily in scenes of gaiety and dissipation, he was recalled from a dissolute life by a singular warning from a Carthusian friar, who pretended that he received a commission from one of the holy brothers of his convent, to predict to Boccacio that his life would be short unless he reformed his licentious manners, and corrected the libertine sentiments of his writings. The superstitious mind of Boccacio was strongly impressed by this strange admonition. He abandoned the study of profane authors, entered into the clerical profession, and became more serious and sober in his habits; and having been employed in a diplomatic capacity at the court of Rome, and in other public affairs, he retired from active life, and died in 1375.

The principal work of Boccacio is *Il Decamerone*, a collection of one hundred stories, which are supposed to have been recited in ten days, to which the title alludes, by a party of both sexes, who had retired from Florence while the plague prevailed in that city. This work, which is partly fictitious, and is a severe satire on the practices of the priests, and some of the doctrines of the Catholic faith, met with great applause, and was translated into different languages; but it abounds with licentious sentiments and indelicate descriptions, although, in common with his other prose compositions, the elegance and purity of the style are conspicuous. Boccacio was the author of numerous other works, some of which were written in Latin and some of them in Italian.

BOCCONIA, *Greater Tree Celandine*, a genus of plants belonging to the Dodecandria class.

BOCHART, SAMUEL, a learned French writer, was the son of a minister of the reformed church at Rouen, where he was born in the year 1599, was remarkable for the early maturity of his genius, and is particularly commemorated as the author of Greek verses in his twelfth year. Having completed his philosophical and theological studies at Sedan, Saumur, and Leyden, he was appointed, on his return to France, to the church of Caen in Normandy, and soon after greatly distinguished himself by his learning and acuteness, in a dispute which he maintained in the castle of Caen, in presence of a numerous assemblage of Catholics and Protestants, with Father Veron, a famous itinerant controversialist. The chief work of Bochart is his Sacred Geography, written in Latin, in which he treats of the dispersion of mankind, and of the colonies and language of the Phœnicians. His researches were afterwards directed to the animals, plants, and precious stones mentioned in the Old Testament; and in a separate publication he treats of the animals of Sacred Scripture. While engaged in a dispute at the academy of Caen, in 1667, he was suddenly carried off by a stroke of apoplexy. To his praise it is recorded, that his modesty and humility were equal to his learning and knowledge. His works have been collected and published in three volumes folio.

BOCNIA, a town of Austrian Poland, in the palatinate of Cracow, and twenty miles distant from the town of the same name, is celebrated for its salt mines and the immense excavations which have been formed in them, in the course of many centuries since their first discovery.

BODMIN, a borough town of Cornwall in England, stands in the centre of the county, and from the numerous monumental remains, supposed to be Druidical, in the vicinity, lays claim to great antiquity. With a population exceeding 2000, Bodmin is now remarkable for its wool market and its manufactures of the same commodity, particularly serges. Bodmin is 235 miles west from London.

BOECE, or BOETHIUS, HECTOR, one of the older historians of Scotland, was born at Dundee in 1470, completed his academical studies at Aberdeen, and afterwards at the university of Paris, where he contracted a close friendship with the learned Erasmus; and being recalled to his native country, was appointed principal of King's College, Aberdeen, with a salary of 40 merks, or L.2, 4s. 6d. Sterling. Gratitude for this distinguished elevation, prompted him, it is said, to compose the *Lives of the Bishops of*

Aberdeen, a large portion of which is devoted to his patron bishop Elphinston, the founder of the college. But his greatest work is *the History of Scotland*, from the origin of the nation; a work which has been the subject of much controversy among later historians, defended by some, and charged by others with the detail of events the materials of which are drawn from fabulous tradition. Boethius is highly eulogised by his friend and correspondent Erasmus, on account of the eloquence of his compositions, and the elegance of his language. He died about the middle of the 16th century.

"Boethius," Dr Johnson observes, "may be justly reverenced as one of the revivers of elegant learning. His style, though perhaps not always rigorously pure, is formed with great diligence upon ancient models, and wholly uninfected with monastic barbarity. His history is written with elegance and vigour, but his fabulousness and credulity are justly blamed. His fabulousness, if he was the author of the fictions, is a fault for which no apology can be made; but his credulity may be excused in an age when all men were credulous. Learning was then rising on the world, but ages so long accustomed to darkness were too much dazzled with its light to see any thing distinctly. The first race of scholars in the fifteenth century, and some time after, were for the most part learning to speak rather than to think, and were therefore more studious of elegance than of truth. The contemporaries of Boethius thought it sufficient to know what the ancients had delivered. The examination of tenets and of facts was reserved for another generation."—"In the present age of trade and taxes," continues he, "it is difficult for the imagination so to raise the value of money, or so to diminish the demands of life, as to suppose 44s. an honourable stipend; yet it was probably equal not only to the needs but to the rank of Boethius."

BOEHMEN, Jacob, denominated the *Teutonic Philosopher*, was a noted German visionary, and was born in a village near Gorlitz in 1575. While engaged in the humble occupation of a shoemaker, he had turned his attention to alchemical researches and astrological studies; and, under the influence of fancied celestial visions, he was seized with the enthusiastic raptures of divine illumination. The fruits of his wild reveries appeared in 1612, in a treatise, entitled, *Aurora*, or *The Rising Sun*, which exhibits, in quaint and obscure language, a strange mixture of alchemy, astrology, and divinity. This work brought down upon him the censure of the civil authorities; and it was not till after the end of seven years that he published various other works, and concluded his labours with a key to his writings. The visionary scenes which appeared to his disordered imagination through life continued at his death. Fancying that he heard sweet music, and receiving an answer to his inquiry what was the hour, it is said he replied that his end was fast approaching; and having taken leave of his wife and family, he expired about the time which he had predicted. This fanatical visionary has not been without followers, both in Germany and Britain, and a translation of his works appeared in England.

BŒOTIA, a kingdom of ancient Greece, which is separated from Attica on the east by mount Cithe-ron, has for its boundary on the north Negropont, Phocis on the west, and the gulph of Corinth on the south. This region is watered by numerous streams; the vallies are remarkable for their fertility, and the hills afford rich pasture to flocks and herds. Many of the places in Boeotia are famous in classical antiquity, among which may be noticed Aulis, a seaport town on the strait Euripus, where the confederated heroes of Greece assembled for their successful expedition against Troy;—Thermopylæ, at the straits of which Leonidas and three hundred Spartans fell gloriously in opposing the immense army of the Persians under Xerxes;—the cave of Trophonius, who was consulted as an oracle, and from which, as the fable relates, no person who ever entered it was afterwards seen to laugh;—and the far-famed mount Helicon, the seat of the muses. The ancient capital of Bœotia was Thebes, and hence the inhabitants of the country were distinguished by the appellation of Thebans more frequently than by that of Bœotians.

BOERHAAVE, Herman, the most celebrated physician of his age, was the son of the clergyman of Voorhoût, a village in the vicinity of Leyden, and was born in 1668. He was originally destined for his father's profession, and with this view his studies at the public school and university of Leyden were conducted. During the intervals of his application to literary pursuits, it was his father's custom to employ him in rural occupations, which he continued through life to love and practise. In his 16th year he was deprived by death of his father, who left behind him a very slender provision for a widow and nine children, of which he was the eldest. This affecting loss seemed to present a serious obstacle to the acquisition of a learned education; but with a firm resolution, and a spirit not to be depressed, he determined to surmount the difficulties of poverty, and to supply by industry the want of fortune.

When he took his degree in philosophy in 1690, he chose for the subject of his thesis the discussion of the distinct nature of the soul and body, and he treated it with such accuracy and perspicuity that he successfully exposed the sophistry of Epicurus, Hobbes, and Spinoza, and equally raised the character of his learning and piety. Divinity and its collateral branches of education continued to be his chief employment; in the pursuit of those studies his slender patrimony was exhausted; and being now compelled to depend for his support on his own active exertions, the proficiency which he had made in mathematical learning enabled him to derive some emolument from the instruction of less advanced students in that science.

A strong bias to medical studies now seized his mind. At first he proposed to himself that they should be only an accompaniment to the study of divinity, which he intended as the serious occupation of his future life; and, in following out his new course of study, he made himself familiar with the structure of animal bodies, not only by the perusal of anatomical works, but also by the dissections and inspection of the bodies of different animals. With this preparatory knowledge, he commenced the arduous task of reading the best medical authors, from Hippocrates to his own time.

Chemistry and botany also obtained a large share of his attention. But with these laborious inquiries his theological studies were not neglected; for still he proposed, as soon as he had advanced to a medical degree, to engage in the cure of souls. Having accomplished this end, he returned, in 1696, to Leyden, with the pious design of undertaking the ministry; but he found, to his surprise, that a rumour which prevailed of the tendency of his opinions to the doctrines of Spinoza, or to atheism itself, was a complete bar to the execution of his plan. Prudence forbade him to struggle against popular calumny, and induced him to relinquish all pretensions to ecclesiastical preferment. With new ardour he resumed his medical studies, and commenced the practice of that profession in which he rose to such distinguished eminence. In the beginning of his medical career his encouragement was not flattering, and his circumstances were by no means easy.

But he was resolved to persevere in the plan which he had formed for himself, determined, if success should be his lot, that it should be the reward of diligence and real merit. Declining the most flattering invitations to settle elsewhere, he continued to employ his time in increasing his knowledge, in visiting the sick, and in teaching mathematics. His appointment, in 1701, to teach the institutes of medicine in the university, extended his reputation. His lectures were heard with great applause, and he was invited by his audience to enlarge the original plan of his course, and to instruct them in chemistry; a task which he undertook, and executed not less to the advantage of his pupils, than to the improvement of the science itself. Having continued in these labours for nine years, he succeeded to the professorship of medicine and botany; and in the latter department of his official duty he greatly enlarged the botanical garden, and enriched it with an immense number of new plants. In 1714 he was deservedly elevated to the rectorship of the university; and in the succeeding year, when he resigned that office, he pronounced an oration on the subject of attaining to certainty in natural philosophy, in which, with the true spirit of science, he illustrates the advantages of experimental knowledge, and reflects with just severity on the arrogance of those who are better pleased with constructing hypotheses than disposed to submit to the toils and drudgery of making observations. In 1718, he was chosen professor of chemistry; and in teaching that science was successful in introducing a perspicuity of arrangement, and elegance of style, which were altogether unknown to its former teachers, or to writers on the subject. In 1722, the course of his lectures and his practice were interrupted by a severe illness; but this afflicting event affords ample proof in what estimation this great man was held by his countrymen. The history of his disorder, which was induced by imprudent exposure to cold, can scarcely fail to excite horror in the reader. For five months he was confined to his bed, where he lay upon his back, unable to attempt the slightest exertion without the most excruciating pain, which deprived him, not only of motion, but of sense. A fortunate remission of his illness took place in the sixth month, which was followed by a recovery greatly desired, but at that time little expected; and when he resumed his official duties, the pleasing event was celebrated with general joy and public illuminations. It is not unworthy of record, that, during the many painful days and sleepless nights which he passed during his illness, he found nothing so effectual in filling up the lingering hours, and alleviating his sufferings, as meditation upon his studies, recollection of what he had read, and a review of those stores of knowledge with which his memory was so amply furnished.

In 1727 he was seized with another severe disorder, which became so alarming that his life was despaired of. The return of his distemper became frequent, and the vigour of his constitution was so exhausted that in 1729 he resigned his professorships; but although he lived with less public employment, his life was not spent in idleness. For, beside the time which was occupied for communicating instruction to his scholars, a large portion was devoted to the cases of patients, who either waited upon him personally for advice, or who consulted him by letter from distant places. His last illness commenced in 1737, and although it was lingering, painful, and afflictive, his firmness and constancy, supported by the warmest piety, and the utmost resignation to the divine will, remained unshaken. On the 23d day of September 1738, when he had reached the 70th year of his age, he was relieved by death from all his troubles.

Thus ended the life of this extraordinary man, whose private virtues, extensive knowledge, and distinguished reputation, have been rarely equalled, and never surpassed. His celebrity as a public teacher drew together crowds of pupils from all parts of Europe; and being well aware that his labours would not be less useful if he studied to recommend truth by elegance, he was not negligent of the embellishments of polite literature in his lectures and writings. His temper was cheerful, and he was always desirous of promoting mirth by facetious conversation; never soured by calumny and detraction; cautious of provoking enemies by severity of censure, he never touched on the faults or defects of others, and never inflamed the envy of rivals by obtruding his own merit; modest, but not timorous, and firm without rudeness, he was neither overawed nor depressed by the presence or insolence of the great.

It seems almost incredible that Boerhaave amassed a fortune of more than L.200,000; and on this account he has been charged with excessive parsimony;—a charge which has been repelled, by stating, that the multifarious avocations of his busy life precluded him from the indulgence of expensive luxury; but perhaps it may be more justly alleged, that his simple habits were altogether incompatible with what may be deemed liberal or profuse expenditure. He rose early, commonly at four in summer and five in winter; devoted his morning hours to study, allotted the middle of the day to public business, and occupied the evening in necessary recreation and amusement. In his dress, he was not more distinguished than the plainest citizen; riding, as long as the distempers with which he was afflicted permitted him to enjoy it, was his favourite exercise; and he derived great pleasure from the garden attached to his country-house, which was stored with great variety of all the plants and herbs which were suitable to the climate.

Boerhaave was the author of numerous works on medicine or its kindred sciences. Of these works the Institutes of Medicine, his Theoretical and Practical Chemistry, and Medical Aphorisms, are the most esteemed, and may be read with advantage at the present day. His elaborate treatise on Chemistry has been translated into English, and his Aphorisms have been illustrated by Van Swieten, in a copious commentary of five volumes.

BOERHAVIA, a genus of plants belonging to the Monandria class, which is so named to commemorate the illustrious Boerhaave, who, amidst his other labours, was an assiduous and successful cultivator of Botany.

BOETHIUS, Flavius Anicius Manlius Torquatus Severinus, an illustrious Roman, and author of a celebrated work, *The Consolation of Philosophy*, was descended from one of the noblest families of Rome, where it is supposed he was born about the year 470. He flourished in the time of the emperors Zeno and Theodoric. His early youth was spent at Athens, where he improved himself in the learning and philosophy of Greece; and returning to Rome, soon rose by his talents and virtues to the chief dignities of the state. His illustrious birth and exalted station, did not prevent him from prosecuting those studies which had a tendency to enlighten and refine his countrymen. With this view, he was anxious to make them acquainted with the arts and sciences which had long flourished in Greece; and he translated, and elucidated by commentaries, the principal works of the Greek philosophers. He filled the important office of consul; he was raised to the patrician rank; and when his sons grew up, he enjoyed the rare and singular felicity of seeing them united in the consulship.

In the struggle which prevailed between Theodoric and the senate, some of whose members had determined to resist the growing tyranny of the emperor, Boethius appeared as the eloquent advocate of his friend Albinus; but asserting the liberties of Roman citizens, and claiming the equal protection of the laws, he was involved in the same charge, and the senate, overawed by the power of the tyrant, reluctantly pronounced the sentence of banishment. Immured in the tower of Pavia, and loaded with fetters, he successfully directed his attention to those sources of intellectual enjoyment which the pursuits and studies of his life so amply furnished. Within the walls of his dungeon, and during the awful moments of suspense that preceded his approaching fate, he composed the Consolation of Philosophy, a work which the voice of succeeding ages has pronounced to be not less distinguished by the sublime morality of its views than the elegance and purity of the language. About a year after his imprisonment, this virtuous philosopher was put to death by the orders of Theodoric; and with Boethius, it is said, the Latin tongue and the last remains of Roman dignity vanished in the western world.

The learning and eloquence of Boethius are conspicuous in his works, which were collected into a folio volume, printed at Venice in 1499. Another edition appeared at Basle in 1570. Boethius was one of the chief writers on music among the Romans; but his principal work is his *Consolation of Philosophy*, which has deservedly retained its popularity through every succeeding age; and among its translators are two royal personages, whose auspicious reigns added peculiar lustre to the throne of England, and whose lives, like the author's, had experienced many vicissitudes of fortune. Alfred the Great produced a version of this work in the Saxon language, and Queen Elizabeth, during her captivity before she ascended the throne, translated it into English. The poet Chaucer also executed the same task.

BOHEMIA, a kingdom subject to Austria, which occupies a central situation in Germany, has Saxony and Silesia on the north, Moravia on the east, Austria on the south, and Bavaria on the west; lies between the 48° and the 51° of north latitude, and the 12° and the 16° of longitude east from London; and extends in an elliptical form about 200 miles from east to west, and nearly 150 from south to north.

Physical state.—It has been maintained that Bohemia, at some remote period in the history of this earth, must have been under water, and constituted a great inland sea—an opinion which derives probability from its external appearance; for it is encompassed with high mountains, while the interior expands into an uninterrupted plain, so that the whole assumes a bason-like form. The highest summit of the western range is elevated 3980 feet above the level of the sea; the northern chain rises to the height of 3780 feet; and the ridge on the eastern and southern frontier 2562. The sheltered hollows of these heights are filled with snow during the whole year; in one place some straggling brushwood crowns the loftiest summits; in another, groups of fantastic peaks shoot up from the mingled confusion of shelving precipices and deep ravines. In the neighbourhood of Adersbach, a space, five miles in length and a mile and a half in breadth, is covered with innumerable columnar masses of sandstone rock, in a perpendicular position, which exhibits to the traveller a grand and singular scene, and presents an object of peculiar interest to the geologist.

Rivers.—No stream traverses the great plain of Bohemia that has not its source in her mountains.—The torrents which rush down their steep declivities are numerous and rapid; and many of them, uniting their waters, form large rivers, which cross and divide the flat country. The Moldau which rises on the southern frontier, the Eger which flows from the mountains near Bavaria, and several considerable streams which rise on the northern side, fall into the Elbe, which traverses the whole of Bohemia from east to west; and having opened a passage for itself through the rocks of the Erzgebirge, continues its course across Saxony towards the ocean.

Climate.—Writers have flatly contradicted each other in their accounts of the climate of this country: one assures us that, as neither lake nor marsh pollutes the atmosphere, the climate is dry, temperate, and salubrious; that the heat of summer is neither intense, nor the cold of winter severe; and that Italy itself cannot boast a finer spring:—while another, with equal claims on our credit, asserts, that the air of Bohemia is dense, damp, cold, and consequently unwholesome, and subjects the inhabitants to more epidemical diseases than fall to the lot of those that dwell in the neighbouring provinces. The truth is probably to be sought for between these extremes. Bohemia is a region placed in a temperate latitude, sheltered from the violence of storms by surrounding mountains, and refreshed and beautified by many living streams—circumstances highly conducive both to the health of its inhabitants and the fertility of its soil.

Productions.—In a mineralogical point of view, this country is interesting above most others; its mountains exhibit, in a successive series, every kind of primary and secondary rock. Many varieties of excellent marble are abundant, as well as mines of of all the common metals; and gems are sometimes found which are held in high estimation. The mineral springs of this country, both cold and hot, are celebrated for their medicinal virtues, and are therefore places of great resort. The soil, though in some places light and sandy, is in general rich and fertile, and brings forth abundantly wheat and other kinds of grain, fruits in great variety and of exquisite flavour, flax and hemp, hops and timber. Nor is Bohemia deficient in animal productions; its cattle are of a good kind; its horses are peculiarly valuable; numerous flocks of sheep, and great herds of swine, are reared for a foreign market; and even the poultry of this country are deemed of a superior quality, and exported in great numbers to the surrounding provinces. Wild-fowl and game are also plentiful, and the Bohemian pheasant is reckoned the most beautiful in the world.

Social state.—Bohemia is said to contain 3,000,000 of inhabitants, who are generally distinguished for beauty of person and vigour of mind. They are described as having high breasts and sparkling eyes, undaunted courage and resolute perseverance. They are well known as excellent soldiers—patient of fatigue, and brave in action. Till very lately villenage prevailed in all its rigour; every man was either a despot or a vassal. In some instances the demands of feudal obligation have relaxed, and it is to be hoped that their remission will pervade the country till they be entirely dissolved. In 1714, this country was divided into twelve circles, through which are distributed 250 cities, 308 borough-towns, 11,455 villages, and 430,000 houses. Prague, the capital, stands on both banks of the river Moldau, fifteen miles in circumference, built on seven hills, and divided into four towns,—the old, the new, the little, and the Radshin towns. A bridge of 18 arches, and 1700 feet in length, connects the new and the old towns together. The churches and palaces of Prague are numerous; it is adorned also with a cathedral rich in relics, by a university founded by Charles IV. and, it is said, contains about 75,000 inhabitants.

Manufactures.—Almost every artificial production which cultivated society requires, is prepared in perfection and abundance. Bohemia manufactures woollen, linen, and silk; leather, stockings, hats, and gloves; pottery, stoneware, and glass; goods in iron, tin, brass, and other metals, both for ornament and use; in her founderies are cast artillery and bells for the whole empire; she excels in the manufacture of paper, mirrors, and flint-glass. For none of the commodities now enumerated has Bohemia occasion to resort to a foreign market; and, after serving herself, she has a considerable surplus for exportation. Many of her manufactured goods find their way into Austria, Turkey, Spain, and Portugal; her cut glass is in demand throughout Europe, and much of it goes to America. The roads are kept in good repair; and in 1749 Maria Teresa, with the view of encouraging commerce, established a regular mail between Vienna and Prague. It is obvious, from these statements, that the balance of trade must be in favour of Bohemia.

Government, &c.—This country is one of the hereditary possessions of the house of Austria, and its affairs are administered by six courts, or councils,—that of the regency, the chancery, the chamber of justice, the chamber of finance, the chamber of fiefs, and the tribunal for deciding the appeals of vassals. Taxes are levied from the land, the mines, &c. and contribute to the state between 15 and 17 millions of florins. The religion of Rome is established; but Jews and Protestants are protected in the rights of conscience by a liberal toleration.

History, &c.—In the remoter periods of her history, Bohemia, with the rest of Europe, was the seat of ignorance and the scene of barbarism; but the detail of the transactions of those times could afford neither instruction nor amusement. In 1275, when Ottocar, who had aspired to the imperial power, fell in the battle of *Weidendorf*, Rodolph I. of Austria, newly rid of his rival, and exhausted with the war, gladly concluded a peace with his widow, and recognised the title of Wenceslaus, her infant son, to his father's crown. His reign was turbulent, and on his death, as well as of that of several of his successors, a multitude of pretenders preferred their claims to the vacant throne, and not unfrequently enforced them by the sword; so that in a long series of years the sovereignty of Bohemia was neither obtained nor held as a peaceable possession. But when Charles IV. had ascended the throne, this hitherto distracted country enjoyed a long period of peace and tranquillity, in which she made rapid advances in science and civilization. Under this mild, but public spirited prince, the laws were reduced into a code which still bears the name of the *Caroline Constitutions*; he excited the industry of his people by enlarging and adorning the capital of his kingdom; and by the encouragement which he gave to commerce, and for the improvement of science and literature, he founded the university of Prague, to which students flocked from all quarters to receive their education among a people now distinguished throughout Europe for learning

Bohemia. and politeness. But, on his demise, through the weakness and wickedness of his sons, who were indolent, quarrelsome, and dissolute, Bohemia became again a scene of usurpation and misrule, which were increased and continued by the Hussite wars that arose and raged with a destructive influence. John Huss, a member of the university, had adopted the opinions of Wickliff of England, and began to inveigh with vehemence against the corruptions of the church. This conduct provoked discussions, in which the citizens sided with the reformer, and the students took part with the pope. A schism was the consequence, and all the foreign professors and students took leave of the university. Huss, and his disciple Jerome, propagated their opinions with equal zeal and success, and sustained persecution with unshaken fortitude, till they were decoyed to Constance, where, after a mock trial, they were committed to the flames.

This tragical event served only to cement the union, and to increase the energy of their party. John Ziska, the king's chamberlain, and an excellent soldier, had been roused to enthusiasm by the new doctrines, and, deeply affected by the fate of their authors, thought of nothing but revenge; and having interpreted some expressions of his master into a sanction of his designs, he left the court, put himself at the head of a small band, which rapidly increased to a mighty army, and proceeded to perpetrate the most wanton and bloody outrages. In 1419, he and his frantic followers slew the magistrates of Prague, broke into the churches, overthrew the altars, and destroyed the ornaments. During these proceedings Wenceslaus, the king, died; his queen, Sophia, assumed the regency, but the castle of Wishbrad, to which she had retired, was invested by so close a siege, that she was glad to purchase a suspension of hostilities by granting an unlimited liberty of conscience. Ziska then retired to the top of a mountain, which, in allusion to that of Palestine, was named mount Tabor, and which he fortified with such skill, that it became a sure asylum to all who fled from persecution. Here he bade defiance to Sigismund, the brother of the late king, though assisted by all the powers of Germany, and encouraged by the exhortations and fulminations of the pope; and the royal troops experienced such great and continued defeats, that the very name of the Hussites became a terror throughout the empire. But internal dissensions soon made them less formidable; two parties arose; and as each happened to be under the influence of reason, or the sway of passion, the partizan became a Calixtin or a Taborite. Sigismund had the address to foment and encourage the opposition of one party to the other; and, after a long negociation, he succeeded, in 1433, in effecting an accommodation with the Calixtins, soon after which the refractory Taborites were subdued.

Charles IV. who was both emperor of Germany and king of Bohemia, had established her rights in the Golden Bull, with freedom from public burdens; but she seldom availed herself of these privileges; and for a long period all connection between her and the empire was nearly suspended, till the crowns were again united in Ferdinand I. He and his successors made several ineffectual attempts to renew the former intercourse; and the only privilege enjoyed by the kings of Bohemia is the right of voting in the election of the king of the Romans.

BOHUS, or BAHUS, a province of Sweden, which has Norway for its boundary on the north, and West Gothland on the east and south, extends about 100 miles from north to south, is copiously watered by numerous lakes and rivers, which are abundantly stored with excellent fish, and timber, pitch, tallow, hides, lime, and fish are enumerated as the principal commodities of exportation.

Boileau. BOILEAU, SIEUR NICHOLAS DESPREAUX, one of the most distinguished French poets of the classical age of literature in the time of Louis XIV. was born in 1636. Descended from a family of lawyers, he was destined for the same profession; and having completed his academical course at the college of Beauvais, his studies were directed to the preliminary knowledge for his future occupation; but it soon appeared that these studies were little congenial to his taste,—and although he persevered till he was qualified for the practice of his intended profession, he at last relinquished it in disgust, and exchanged it for that of theology, which, in its turn, was soon abandoned as equally repulsive. Thus unfettered by any professional avocation, he resolved to indulge his passion for literary pursuits, and he returned with fresh ardour to poetry, from which, during his academical course, he had acquired considerable reputation. The Satires of Boileau, which appeared in 1666, exhibited to the public the most decided proofs of the powers and vigour of his genius, his sound judgment, and correct taste. The *Lutrin*, a mock heroic poem, which was published 1674, and in 1683, in six cantos, affords an excellent specimen of his talent for humorous description. This poem, the subject of which is a dispute between the treasurer and chanter of the holy chapel at Paris concerning the position of a reading desk, has been compared to the celebrated Rape of the Lock of Pope, from the similarity of character and humour which prevail in both productions, although it has been generally admitted that the superiority in fancy and execution belongs to the English poet, and in this judgment Voltaire himself has not hesitated to acquiesce. The critical skill of Boileau appeared in the *Art of Poetry*, and a translation of *Longinus*, which latter he enriched with many valuable notes.

The poetical productions of Boileau obtained for him not only the favour of Louis, but the more substantial reward of a pension, and the appointment, in conjunction with his friend, the celebrated Racine, of historian of the reign of that pompous monarch,—an appointment, it may be observed, which produced nothing, for the task which the associated poets had undertaken was never executed. The admission of the poet into the learned academies of France, which in most cases may be regarded as a matter of course, or of interest, need scarcely be noticed; and the detail of the controversy concerning the comparative merits of the ancient and modern authors, in which Boileau took a decided part, and much literary violence and personal animosity prevailed, could afford neither instruction nor amusement. He died in 1711, when he had reached the 75th year of his age.

BOILING, or Ebullition, is the agitation of a liquid when it is converted into vapour by the application of heat. As the heat is generally applied to the bottom of the vessel, the lowest stratum of liquid is first converted into the state of vapour, or steam, and this steam rising through the liquid produces the bubbling, or agitation, which is more or less violent in proportion to the heat applied. See Chemistry.

BOIS-LE-DUC, the capital of Dutch Brabant, stands at the confluence of the rivers Dommel and Aa, in a plain, which is nearly surrounded with morasses, is a place of considerable antiquity, strongly fortified, and defended by a castle. The approaches to the town, on the land side, are by causeways, and, by water at three separate gates. The cathedral, built in 1366, and reckoned one of the most magnificent structures in the Low Countries, was remarkable for a lofty wooden tower, supported by four stone pillars; but it was destroyed by lightning about the end of the 16th century. While in the hands of the catholics, the churches and other religious houses, some of which have been converted into warehouses, were numerous; and as the place is intersected by many canals, the accommodation of a great number of stone and wooden bridges is necessary. The population of Bois-le-Duc is about 10,000, and the chief manufactures are confined to linen cloth and different kinds of hardware.

BOKHARIA, an extensive region of Tartary. See Bucharia.

BOLCA-MONTE, a hill near a village of the same name in the Veronese territory in Italy, and about 20 miles distant from the city of Verona. Monte-Bolca has been long the subject of investigation and speculation among naturalists, on account of the extraordinary abundance of vegetable and animal petrifactions which it contains, and which clearly prove, although it is now not less than 50 miles distant from the sea, that it must have been at some remote period immersed in its waters. The rocks of which this hill is composed are of a marly or calcareous nature, and of a slaty structure. The summit consists of columnar basalt; but the most singular feature in the natural history of Monte-Bolca, is the prodigious accumulation of almost every kind of land and sea animals in a petrified state, as the remains of larger quadrupeds, birds, fishes, insects, and zoophytes; and it is not the least remarkable circumstance, that these organic remains have belonged to animals the species of which, in the present condition of the world, inhabit very different regions of the globe. Of the petrified fishes nearly one hundred different species have been discovered, most of which are now natives of the seas or rivers of Europe, but some of them are only found in the rivers of India and America.

BOLE, an absorbent earth, of which numerous varieties have been described by the older naturalists. See Mineralogy.

BOLETUS, a genus of plants belonging to the order of Fungi, under the Cryptogamia class.

BOLOGNA, or Bononia, a city of Italy, and capital of the duchy of the same name, stands in a beautiful plain at the foot of the Apennines, and on the banks of the rivers Savena and Rheno, is of an oblong form, five or six miles in circumference, and encompassed with high brick walls. The houses, which are flat-roofed, are in general built on arcades, the pillars of which are of wood or stone. The pavement for carriages is considerably lower than the porticos for foot-passengers; and as the streets are narrow, they present a gloomy aspect.

In the public buildings of Bologna, art seems to have exhausted all her resources, whether the grandeur of the designs, the magnificence of the structures, the splendour and variety of the decorations, or the unrivalled specimens of the productions of the pencil or of the chisel by the most celebrated masters, with which they are adorned, be considered. The public palace is one of the noblest buildings of the city. In this spacious edifice the municipal government and the courts of justice are accommodated; some of its apartments are appropriated to the museum of the celebrated naturalist Aldrovandi, and to a valuable collection of medals; and an extensive arsenal for military stores is included within its walls. The private palaces are also numerous and splendid; and the churches, the number of which is said to be not less than 200, exhibit a remarkable display of architectural beauty and elegance; and, when it is added, that few of them are unadorned with the most exquisite productions of the graphic art, furnished by the Caraccis, Albani, Guido Rheni, Raphael, Guercino, and others, the traveller who admires their genius and their works will not fail, when opportunity offers, to indulge his taste in contemplating these noble efforts of human skill.

The tower of Asinelli, which derives its name from the person by whom it was constructed in the beginning of the 12th century, stands in the centre of Bologna, and is not less remarkable for its great height, rising 370 feet from the ground, than for its inclination, which is more than three feet from a perpendicular position. But this inclination is exceeded by another tower, which has the appropriate appellation of the *leaning tower of Garisenda*, is 144 feet high, and deviates from the perpendicular more than eight feet. The elevation was originally much greater, but the instability of the foundation occasioned the fall of part of it, or required it to be taken down for safety.

The university of Bologna, founded in the early part of the fifth century, became a celebrated school of law, and attracted an immense concourse of students from all quarters. The college in which the sciences are taught still retains considerable celebrity; and the institutions for the improvement of the fine arts are numerous and excellent.

The population of Bologna is estimated at 70,000. The manufacture of velvets and other kinds of silk stuffs has been continued for nearly five centuries. To these are added the manufactures of crapes, gauzes, damasks, paper, and playing cards. For throwing silk and preparing it for the various fabrics for which it is destined, as well as for numerous other purposes, extensive machinery, driven by water, has been erected on the banks of the Rheno in the vicinity of the city. The trade with other towns of Italy, which is greatly facilitated by means of water-carriage, and with Venice, Germany, and France, in the various natural and artificial productions, such as hemp and flax, hams, dried tongues, sausages, maccaroni, olives, perfumes, and essences, beside the produce of the silk manufacture, is very considerable. The fertility of the soil, and the perfection of the cultivation, give to the surrounding territory all the richness, variety, and beauty of an extensive garden. The soil and climate are peculiarly favourable to the culture of the olive and the melon, and are equally congenial to the growth of tobacco; hemp shoots up with remarkable luxuriance; and the warmth and shelter afforded by the rows of mulberry trees and elms which surround the vineyards, elaborate and improve the juice of the grape.

Bologna seems not to have been a place of much importance in the flourishing periods of the Roman republic; it rose to eminence on account of its learned institutions about the 13th century; possessed some degree of independence under the German emperors; and when, by civil dissensions, it fell under the papal dominion, it still retained some of its ancient privileges and former distinction. In its civil polity Bologna presented the semblance of a republican form of government; the French became its masters in 1796, and, with other territories of Italy, it formed part of the Cisalpine republic; but since that immense fabric of usurped dominion has fallen, it has been no doubt restored to its original constitution.

BOLOGNIAN STONE, or SPAR, is a native sulphate of barytes, or heavy spar, which was first found in the neighbourhood of Bologna, from which the name is derived. After being exposed to strong heat, for the purpose of extracting the precious metal which it was supposed to contain, it emitted a phosphorescent light. See MINERALOGY.

BOLSENA, a town of Italy, which stands on a lake of the same name, encompassed with mountains covered with wood, is a place of no great importance, although it is surrounded with walls, and flanked with towers. The ancient Volsinium, one of the finest cities of Etruria, the temples and squares of which were adorned with 2000 statues, stood in the vicinity of Bolsena, and the ruins still furnish to the antiquary beautiful specimens of Roman art, in curious marbles and sculptured ornaments. The lake is 30 miles in circumference,—is the great resort of numerous water fowl,—is abundantly stored with various kinds of fish, and is remarkable for the extraordinary size of its eels. Two islands in the lake are occupied with religious houses, one of which contains a convent, to which extensive gardens are attached; and the other, a small spot, includes only a hermitage with its chapel. According to fabulous antiquity, these islands floated about in the lake, and this incredible story is alluded to by Pliny.

BOLSOVER, a town of Derbyshire in England, is situated on the declivity of a steep hill, is a place of great antiquity, and seems to have been protected by a strong castle, on the site of which a modern structure is raised. The manufactures of various kinds of hardware, once considerable, have been transferred to Birmingham; but it still retains its celebrity for tobacco pipes, which are reckoned the best in the kingdom. The population is estimated at 1000.

BOLTON LE MOOR, or BOLTON IN THE MOOR, a town of Lancashire in England, is divided by a rivulet into two parts, denominated Great and Little Bolton, and has been famous from the earliest times for its manufactories. The population, in 1773, was little more than 5000; in 1801 exceeded 17,000; and in 1811 had increased to 24,000. The annual returns from the manufacture of fustians, calicoes, dimities, counterpanes, muslins, and all other kinds of cotton goods, are estimated at more than one million Sterling. The Wigan cannel coal, in the vicinity, furnishes employment to some of the inhabitants of Bolton, in making various utensils and trinkets of that substance, which takes a fine polish, and is converted into snuff-boxes, candlesticks, &c. The inland navigation affords numerous facilities to the manufactures and trade of this place.

BOMBAX, the SILK COTTON TREE, a genus of plants belonging to the Monadelphia class.

BOMBAY, an island on the western coast of India, about ten miles in length, and three in breadth, situated within the 19th degree of north latitude, and the 73d of longitude east from Greenwich, and is one of the three English presidencies in that part of the world.

Productions.—This island, being full of inhabitants, is in a high state of cultivation, although not remarkable for its fertility; but it is celebrated over the east for the excellence of its onions; the common and sweet potatoe are also raised in it of a good quality; rice is cultivated, as in the rest of India; cocoa nuts are abundant, and other fruit trees indigenous to the climate; buffaloes, sheep, goats, and poultry are plentiful; game, such as red-legged partridges and snipes, is not scarce; the shores are also frequented by fishes of various kinds and of excellent quality; of these the prawn is uncommonly fine, as also the *bumbelo*, resembling a large sand-eel, which is dried and eaten to breakfast; the frogs grow to a large size, and are sometimes eaten both by the Portuguese and the Chinese.

Inhabitants.—The human beings residing in Bombay are estimated at 220,000. Of these, three-fourths are Hindoos, 8000 are Mahometans, 8000 are Parsees, 4000 are Jews; the rest are Portuguese, English, &c. The Parsees, who are Persian emigrants, and disciples of Zoroaster, dwell chiefly in those districts which are under the jurisdiction of the president of Bombay. They still adhere to their ancient customs; they wear an Asiatic dress; they adore the sun, the sea, and fire. They have a singular mode of interring their dead. For this purpose, a piece of ground is surrounded with a triple wall, having a well sunk in the centre. In the space nearest the well they deposite their children taken from them by death; the outer division is alloted to the males, and the intermediate one to the females. Here the bodies are exposed till their flesh is devoured by vultures, when the friends with pious care collect the bones and throw them into the well. The Parsees are an active and an industrious race; the soil is chiefly in their possession, which they cultivate with care; they make excellent ship-builders, and patient labourers. Almost every mercantile house has a Parsee partner, who generally advances the principal part of the capital; and in every respect this tribe contributes greatly to the prosperity of the settlement. The liver complaint is the most prevailing disease of Bombay, and exposure to the night breeze is apt to induce fever. In other respects it is not unhealthy.

City.—The town of Bombay was originally built and fortified by the Portuguese; but it has been greatly enlarged and strengthened since their time. It is now about a mile in length, strongly defended on all sides, especially towards the sea, where it is deemed impregnable. The fort is washed on three sides by the waves, and presents a very imposing appearance. The English have a church within the fort; a presbyterian church has been lately erected; and the Portuguese, the Armenians, and Jews, have places of worship both in the town and the suburbs. The houses consist chiefly of a single story, and, contrary to the Indian mode of architecture, have sloping roofs covered with tiles. The English have country houses, which generally command delightful prospects.

Commerce.—Bombay has attained to greatness, and derives the whole of its present importance from its facilities for commerce. Its capacious harbour, capable of containing more than 1000 ships of burden, is sheltered on all sides from the violence of the waves. Its situation commands an easy access to the richest and the rarest productions of the most favoured regions of the earth. Hence, it has become the centre of the entire trade of the north-west coast of India. Cotton is the principal commodity, which is collected from all the neighbouring districts and exported to China. But this place is also the depot of sandal-wood, pepper, &c. from the Malabar coast; of gums, drugs, coffee, and pearls from Persia, Arabia, and Abyssinia; of ivory, precious stones, piece goods, and other manufactured commodities, from Cambay, &c.; of sharks' fins, birds' nests, &c. &c. from the Maldive and Lacadive islands; and of manufactured goods, porter, grain, &c. from England. From this great mart, thus composed of such various productions, and collected from so many places, many ship loads are annually exported to numerous and far distant countries. The most of the cotton, a great deal of manufactured goods, wine, &c. are carried to China. The produce of Gujrat, of Persia and Arabia, and the manufactures of Cashmere, Surat, &c. are annually transported to England. The goods of this market are also in demand in Goa and the Brazils, as well as in all the countries and districts in the north and west of India, so that both the import and export trade is prosperous. The most of this trade is carried on in English bottoms. The ships which are built here of teak timber are said to be greatly more durable than other Indian-built vessels. The teak is brought from the mountains of Gujrat, or from Rangoon, a Birman sea-port.

Establishment.—The president of Bombay's jurisdiction extends over the districts of Surat, Broach, Cambay, Gochwarah, and other countries in the province of Gujrat, by far the most fertile, populous, and best cultivated region in India, abounding in large towns and excellent harbours. A single judge, with the title of recorder, holds a court of judicature, to which three barristers and eight attornies are attached. The whole establishment of Bombay consists of about 75 civil servants, 550 military officers, and 21,000 soldiers, 40 surgeons, and five chaplains, the annual expence of which amounts to L.373,359. The Company's marine, to protect the trade, consists of 15 ships of war, armed boats, advice boats, and others, which give employment to a considerable number of officers and men.

History.—The Portuguese obtained possession of the island of Bombay in the year 1530, and, delighted with the fineness of its harbour, they built on its shore a town and a fortress. But it was too near their capital Goa to rise, under them, to any high degree of importance. When Charles II. married Catherine, the princess of Portugal, this island was ceded to him as part of her portion. The king, however, having learned that the traffic which his servants carried on in this newly acquired possession, injured the regular commerce of the English East India Company, transferred it, by letters patent from the crown, to that body, on condition of their paying the annual rent of L.10 in gold; and, in consequence of this transaction, Sir George Oxinden, the Company's governor, received possession of the island of Bombay, with the garrison, the arms, ordnance, and stores.

The revenue of this establishment was, in 1668, nearly L.7000. About this time a mint was established, where rupees and other Indian money were coined. But it still continued unhealthy, and exposed to the depredation of the Mahratta pirates; and though the garrison consisted of 400 regulars and 300 militia, and 100 cannon were mounted on the fortifications, the vigorous government of Aurengzebe and the other native powers on the coast, kept it in a state of perpetual alarm.

After the capture of Bantam by the Dutch in 1684, the court of directors constituted this station an independent settlement, and the seat of the trade and power of the English nation in the East Indies. Two years afterwards the English government of Surat was also transferred to this island, and about the same time it was infested by enemies and afflicted by the plague. In 1700, Sir Nicolas Waite, the English Company's resident at Surat, procured, by means of his intrigues, the imprisonment of Sir John Gayer and Mr Colt, the Old London Company's servants. On the union of these two rival bodies in 1708, Sir Nicholas was dismissed, but Gayer and his associate were not released from their confinement. At this period the settlement was so much distracted by faction, so closely invested by enemies, and so dreadfully reduced by the plague, that, to conceal its weakness, its governors declined to receive an envoy from the king of Persia.

Such was the original condition of this important settlement, which thus by slow degrees, and amid disastrous circumstances, has become one of the greatest commercial stations of the east. In 1802 it obtained an accession of territory from Anund Guicowar, a Mahratta prince; the island of Bombay has also been lately united to that of Salsette by means of a causeway; and at present the jurisdiction of this presidency extends over a considerable part of the adjoining coast, and even exerts a sensible influence in Persia and Arabia. The travelling distance from Bombay to Calcutta is 1300 miles.

BOMMEL-WAERT, the *Insula Batavorum* of Cæsar, is an island of Holland, which is formed by the rivers Meuse and Waal; is about fifteen miles in length, and six miles in breadth, contains Bommel and some other towns, with several forts for its defence, and possesses in many places a rich and fertile soil, which produces abundance of corn and fruits.

BOMMEL, the chief town of Bommel-Waert in Holland, stands in a fine plain, which is remarkable for its fertility and vegetable productions, includes about 3000 inhabitants, and at one time enjoyed an extensive trade, which, on account of the difficult access to the harbour, occasioned by sand banks, has been transferred to Bois-le-Duc.

BONA, or BONNE, a sea-port town of Algiers, in Africa, formerly the capital of the province of the same name, supposed by some to be the ancient Hippo, and was once distinguished for trade, wealth, and population. The surrounding territory produces abundance of corn, fruits, and cattle; and the exportation of grain, oil, hides, wax, and wool, by the European mercantile establishments, was the principal source of the commercial prosperity of Bona. A valuable coral fishery on the banks in the bay is successfully prosecuted by the Genoese and the natives of other states of Europe; and it is said, if properly regulated and encouraged, might afford profitable occupation to 10,000 men.

By a contract entered into with the dey of Algiers in 1806, Bona and some neighbouring places were to be put in possession of the British, for the purpose of forming commercial settlements, and the stipulated sum of 11,000 Sterling was paid for the privilege; but it is not understood that any establishment was made.

Bona was the scene of a most barbarous outrage on the Christians engaged in the coral fishery in 1816. To check the predatory practices of the Algerines and other Barbary states, and particularly to force them to abolish the disgraceful slavery to which they doom their unfortunate Christian captives, under the too lenient connivance of the European powers, a British squadron, under Lord Exmouth, appeared before Algiers, and obtained a compliance with the reasonable conditions required; that peace should be made with Sicily and Sardinia, that their captives should be restored at a moderate ransom, and that all future prisoners of war should be treated according to the usages of civilized nations. But the British admiral, after concluding the treaty, had no sooner left the coast, than it was violated by the perpetration of a dreadful massacre of the crews of some hundred Neapolitan boats engaged in the coral fishery on the coast. This cruel massacre was the consequence of a premeditated design. A gun fired from the castle was the signal of attack on the defenceless fishermen; two thousand Moors and Turks rushed upon them, and, supported by the guns from the forts, involved the whole in indiscriminate carnage, so that not one escaped. The British flag, under the sanction of which the fishing operations were carried on, was torn down and treated with the utmost indignity. This inhuman outrage brought on these rapacious barbarians the signal chastisement which was inflicted by the same admiral on the memorable 27th of August of the same year, and thus led to the unconditional acquiescence of the dey of Algiers in the terms proposed by the British government.

BONAIR, or BUEN-AYRE, an island which lies on the north coast of South America, 30 miles east from Curaçoa, about 50 miles in circumference, with a good harbour on the south-west side, and produces maize, yams, and potatoes, some part of which is exported to Curaçoa. Cotton is also among the vegetable productions of Bonair, and some cattle and goats are reared.

BONAVISTA, or BUENA-VISTA, so denominated from the delightful aspect which it presented to the first discoverers in 1450, is one of the Cape de Verd islands, about 50 miles in circumference, has two bays which admit ships, and which are distinguished by the names of English and Portuguese bays, but are both somewhat inconvenient on account of shoals and banks, and is said to contain about 8000 inhabitants. The maritime parts of the island are low, but the central regions rise into hills; the soil is light and sandy, and not well cultivated; and salt, cotton, and indigo are the chief productions. Milk, goats flesh, fish, and turtle, furnish the principal food to the inhabitants; and their superabundant produce is exchanged with English vessels for old clothes, meal, and biscuit. Cotton and indigo would thrive well in the soil and climate; but the natives are indolent, and careless in the culture of the former, and follow a very rude process in the manufacture of the latter.

BOND, a deed or written obligation, by which a person binds himself, his heirs, executors, and administrators, to perform some act, or to pay a certain sum of money to another at a fixed time. In this form a bond is called a simple obligation. But there is generally a condition added, that if the person bound does some particular act, the obligation shall be void, or shall remain in full force; and in case this condition is not performed, the bond becomes forfeited, or absolute at law, and charges the person bound while living, and after his death the obligation descends upon his heir, who is bound to discharge it.

If any condition of a bond be impossible at the time of making it, or if it be contrary to some rule of law, that is, merely positive, or if it be uncertain, the condition alone is void, and the bond shall stand single and unconditional. If the condition be an obligation to perform something that is immoral in itself, that obligation is void; and if the condition be possible at the time of making it, but if it become impossible by the act of God, the act of the law, or the act of the obligee himself, the penalty is saved, because no prudence or foresight of the person bound could guard against such contingency.

When no time is fixed for the payment of a bond, it is then held to be payable on demand; but, even in this case, a reasonable time is allowed by the courts of law for the payment. On the forfeiture of a bond the whole penalty was formerly recoverable by law, but courts of equity do not permit more than the principal, interest, expenses, and reasonable damages sustained by non-performance of the conditions; and by special statute it is ordained, that in case a bond for the payment of money be forfeited, and a suit commenced, the tender or payment of the principal sum, interest, and costs, shall be a full satisfaction and discharge. Blackstone's *Commentaries*.

By the law of Scotland a bond is either *heritable* or *moveable*. All bonds which bear a clause of infeftment, beside the personal obligation to repay the principal sum and interest, are heritable. Bonds merely personal have been always considered moveable before the term of payment, but afterwards they are held to be heritable. But by statute 1661, all sums in contracts and obligations are made moveable in regard to succession; but in reference to the fisc, and the rights of husband and wife, they continue heritable, with the exception of bonds bearing an obligation to infeft, and such as are payable to heirs and assignees, secluding executors, which are in all respects heritable.

A bond which is payable to heirs, without any mention of executors, descends not to the heir in heritage, but to the executor; but a bond which is taken payable to heirs-male, or to a series of heirs, is heritable; and bonds which are originally moveable, may become heritable, either by destination, or in consequence of a supervening heritable security. All bonds, whether they are personal or heritable, before seisin, may be affected by creditors, either by adjudication or arrestment.

BONDOU, a district or kingdom of Africa, which is included between the rivers Gambia and Senegal, and has for its boundaries on the east and south-west Bambouk and Wooll; is an elevated region, many parts of which are covered with woods; the Faleme is the principal river; and a large proportion of the district is said to be fertile in grain. Fatteconda is the principal town; and the inhabitants in general, who are said to be remarkable for their industry, are chiefly occupied in agriculture and the rearing of cattle. The Mahometan faith has been established, and the natives are represented as being very exemplary in the observation of its laws and the practice of its precepts. The Arabic language is spoken by the inhabitants of Bondou, and this may be regarded as a natural consequence of the introduction of the Mussulman religion. A French traveller, who visited this country in 1786, describes the village of Coursan as the residence of the king. This place is fortified with palisades, and is supposed to contain more than a thousand inhabitants.

The inhabitants of Bondou belong chiefly to the Foulahs, who are of a yellow complexion, with small features and soft silky hair, naturally, it is said, of a mild disposition, and gentle and tractable in their manners. The trade in slaves was at one time considerable, and the barter of corn for iron, gold-dust, and different kinds of gums, is still carried on. A coarse cotton cloth is manufactured and dyed with the cotton and indigo produced in the country. Ivory is also a valuable commercial commodity in Bondou. But after all that has been said by travellers of the abundance and profusion which the inhabitants of this region enjoy, of the wisdom of their government and laws, and particularly of their moderation in giving no encouragement to religious persecution, it cannot be doubted, from the relations of the same travellers, that they are not less barbarous than the other natives of that uncivilized country, and not less rapacious and oppressive in their exactions from strangers. The first question put to the French traveller already alluded to, when he was admitted to the presence of the king of Bondou, was a demand for presents; and no small disappointment was expressed when none was produced, and a threat was offered that he would not be suffered to depart.

BONES, the solid parts of animal bodies; for an account of the structure and uses of which, see ANATOMY.

BONN, an ancient city of Germany, and the usual residence of the electors of Cologne, occupies a fine situation on the left bank of the Rhine. The streets are generally narrow; the cathedral, the town-house, a Gothic structure adorned with paintings, and the palace of the elector, a magnificent edifice erected in 1777, are the principal buildings. The great rampart affords a very extensive and delightful view of the course of the Rhine and the adjoining country. The population is estimated at 9000. The mineral springs at the distance of three miles from Bonn have acquired considerable celebrity, and, before the revolution, were much resorted to; but the military occupation of the place by Bonaparte was fatal to the fine walks, pleasure gardens, and elegant buildings, which were laid out and constructed by the electors for the accommodation of visitors.

BONNER, EDMUND, an English bishop, whose vindictive spirit, religious zeal, and versatility of opinions have given his name a conspicuous place in the history of the times in which he lived, was a native of Worcestershire, and, according to one account, was the natural son of a priest, but, according to another, was descended of parents in humble life, the place of whose residence, it is said, still retains the name of *Bonner's Place*. Admitted as a student at Oxford in 1512, after seven years residence he took his degrees in canon and civil law, was soon after ordained and appointed to a living in the church. With the reputation of an able politician, he was fortunate in obtaining the favour and patronage of the celebrated cardinal Wolsey, who raised him to offices of high trust, and loaded him with ecclesiastical preferments. Besides being archdeacon of Leicester, and a prebend of St Paul's, he held livings at the same time in Yorkshire, Worcestershire, and Norfolk. The disgrace and death of his patron, the ambitious cardinal, did not interrupt the fortunate career of Bonner, for he was successful in obtaining the favour of Henry VIII., was appointed one of his chaplains, and proved a useful instrument in the hands of that tyrannical monarch, in promoting his divorce from queen Catharine, and in abrogating the supremacy of the pope in England.

In the violent struggle which Henry maintained with the papal court, Bonner was twice sent to Rome to appear on behalf of his sovereign; and on one occasion his firmness of conduct, or rudeness of manner, drew from the pope a violent threat of summary vengeance on his person. Dreading the consequence, he deemed it most prudent to withdraw;

and having returned to England he was promoted, at the recommendation of the reformers, first to the see of Hereford, and soon after to that of London.

During the reign of Henry, Bonner was an active and zealous opponent of popery; but when he had obtained high preferment in the church, or had changed his views, he refused to take the oaths of abjuration and allegiance on the accession of Edward VI. His commitment to prison produced a recantation and submission, which were followed by his enlargement. But his private conduct did not correspond with his public professions, for he was still disposed to support the cause and promote the re-establishment of popery; and, after a minute enquiry under the authority of a commissioner, and a long trial, during which, it is recorded, he behaved more like a madman than a bishop, he was again sent to prison and deprived of his bishoprick.

The accession of Mary in 1553 was a fortunate event to Bonner, in restoring him to his honours and emoluments, while it afforded an opportunity of a full display of his natural disposition and true character. Elevated to the high station of president of the convocation in place of archbishop Cranmer, who was degraded and sent to the Tower, he began the dreadful work of persecution, with a perseverance and cruelty which have been rarely equalled. Exclusive of those who were subjected to imprisonment, public whipping, and severe torture, it is said that not fewer than 200 persons perished in the flames, by his agency, within the short period of three years.

The accession of Elizabeth in 1558, produced a favourable change to the persecuted reformers. Bonner appeared among the protestant bishops who congratulated the queen on that event; but his doubtful character seems to have excited suspicion in that princess. He was coolly received, lived for some time unnoticed, and probably foreseeing the fate that awaited him he refused to take the oaths, was degraded and committed to prison, where he died, after ten years confinement, in 1569. To prevent the indignity and violence of the irritated populace, his body was privately interred.

The narrative of this prelate's life affords ample evidence that he was of a violent temper and cruel disposition, actuated by strong ambition, and little scrupulous of the means he employed in promoting his views; but the bloody persecution which he instigated, during the reign of Mary, must remain an indelible stain on his memory.

BONNET, Charles, a distinguished naturalist, was descended from a French family, who had fled from their native country on account of religious persecution, and who had taken refuge in Switzerland, and was born at Geneva in 1720. He was an only son, and his father bestowed a large share of attention on his education; but either his dislike to the dry study of grammar, or a deafness with which he was early afflicted, rendered his progress in education at the public school less rapid than his friends expected; he was afterwards intrusted to the care of a domestic tutor, and, under him, his advances in general learning were promising and successful. At the early age of sixteen, his taste and bias for the study of natural history seemed to have been completely formed; and the perusal of Reaumur's Memoirs on Insects led him to repeat and extend the curious observations and experiments of that illustrious naturalist,—the details of which being communicated to him, excited no small degree of admiration of the sagacity and acuteness of the young philosopher.

Destined by his father for the profession of the law, Bonnet entered reluctantly on the requisite studies; but this was merely a formal acquiescence, and regarded as an unwelcome task, for his inclination led to very different pursuits, and his mind was occupied with other objects. Beside other investigations in natural history in which he was engaged about this time, he communicated, in 1740, to the academy of Sciences, the result of a curious inquiry respecting the multiplication of *aphides*, or tree-lice; and in the succeeding year he instituted an interesting series of experiments on the effects that follow the division of worms, from which it appeared that many species possessed, in some degree, the same remarkable reproductive powers as the polype. The minute observations in which he had been long engaged, and particularly the constant use of the microscope, which was necessary in the prosecution of some of his inquiries, greatly affected his eyes, as well as his constitution, and obliged him for a time to decline every kind of study. The temporary relaxation which he enjoyed materially improved his health, and again enabled him to resume his inquiries concerning vegetation. The ascent of the sap, and the action of the upper and under leaves of plants were the next subjects which occupied his attention, and the result of his labours appeared in a separate publication.

From physiological studies Bonnet turned to metaphysical speculations, and soon became a voluminous writer on this fruitful subject of inquiry. His *Essay on Psychology*; *Analytical Essay on the Faculties of the Soul*, *Contemplations on Organised Bodies*, and *The Contemplation of Nature*, successively appeared, and met with approbation and applause. The last production of Bonnet is entitled *Palingenesie Philosophique*, and treats of the past and future state of living beings; and to this work is annexed an inquiry into the evidences of the Christian revelation and the doctrines of Christianity. Some other subjects of natural history again attracted his attention, and occupied part of his leisure in the remaining years of his life; and although he was attached by inclination and habit to studious retirement, he did not altogether relinquish the social duties of a citizen. For the period of sixteen years he was a member of the great council of the republic, and often distinguished himself by his manly eloquence in the support of wise and moderate measures, and in the cause of morals and religion. The last labours of the philosopher were devoted to the revisal and correction of his works, which were published in a general collection, in nine volumes quarto. They are all written in the French language, but many of them have been translated into English and other languages. He died in 1793, at the advanced age of 73; and such was the respect in which he was held by his countrymen, that public honours were paid to his remains.

BONNETIA, a genus of plants belonging to the

Polyandria class, and so denominated to commemorate the name of the great Swiss naturalist.

BONONIA, a city of Italy. See BOLOGNA.

BONONIAN STONE, a mineral substance, which has received this name from being found near Bononia in Italy, and which, after being subjected to heat, gives out light in the dark. This mineral is heavy spar, or sulphate of barytes. See CHEMISTRY.

BONONIAN JAR, OR BOTTLE, denominated also Philosophical Phial, is a thick glass-jar which has not been subjected to the process of annealing, and which exhibits the singular property of breaking into minute fragments, when a small bit of flint is dropped into it, although it is capable of bearing a considerable blow externally. See ANNEALING.

BONPLANDIA, a genus of plants belonging to the Pentandria class, and so named in honour of the enterprising traveller who accompanied Humboldt in his arduous journey through South America.

BONTIA, a genus of plants belonging to the Didynamia class.

BONZES are priests or monks in eastern countries, who are devoted to the religion of Fo, are very numerous in those regions where that superstition prevails, and are distinguished by different names. In the kingdom of Siam they are denominated *Talapoins;* in China they are called *Ho-chang;* in Tartary *Lamas;* in Japan the usual appellation is *Bonzes;* and by this latter name they are generally known in Europe. The institutions of the Bonzes have some resemblance to the monastic establishments of the church of Rome; they live in separate communities, and in retirement from the affairs of the world, bind themselves by vows of perpetual celibacy, and attach themselves to particular pagodas or temples. Female institutions of Bonzes are also known in some of the countries of the east. As the doctrine of the transmigration of souls is a tenet of general belief in Asiatic regions, temples are erected to different kinds of animals, which thus become the objects of public veneration and worship, from the notion that the soul of the god in his various transmigrations may have occupied their bodies. On this account the worship of the god Fo is conducted by these devotees under the form of different animals into which he is supposed to have passed in the various stages of his existence.

The Bonzes are very numerous in some parts of China, many of their establishments are richly endowed, and possess extensive domains; and as a great portion of their revenue depends on the superstitious veneration in which they are held by the people, they have had recourse to the various arts of mendicity to increase their income. To excite the commiseration of their countrymen more effectually, and to increase the liberality of those who are disposed to give them alms, they subject themselves to the severest mortifications, and sometimes to the most painful sufferings, appearing in the public places loaded with heavy chains, cutting and mangling their bodies till they stream with blood, carrying burning coals on their bare head, and examples are not wanting of some who inclose themselves in narrow boxes or cases stuck full of sharp nails, so that the flesh is torn by the slightest motion. But besides these open means of obtaining charity, the Bonzes are charged, and perhaps justly, with practising the most nefarious arts of imposture and fraud in exciting the beneficence of the public, and the dissolute lives of some are remarkable for selfishness, profligacy, and cruelty. With all the superstition of the Chinese, the Bonzes are held in great abhorrence by that people, and their detestable practices meet with frequent and severe checks from the public authorities. In the northern part of China these devotees are little encouraged, and the pagodas to which they were attached are now greatly neglected, and most of them have fallen into decay.

BOOBY, a sea bird belonging to the genus Pelican. See Pelicanus under ORNITHOLOGY.

BOOK, a general denomination for any literary composition, but, in a more restricted meaning, is applied to such works of this description as are of sufficient magnitude to form a volume. Smaller productions are distinguished by the name of pamphlets; and from the size or form of books appropriate appellations have arisen. When the whole sheet is employed, the book is said to be in *folio*; when the sheet is folded once, and thus forms four leaves, or eight pages, it is said to be in *quarto*; and when the sheet is folded twice, it makes eight leaves, or sixteen pages, and is then called a book in *octavo*; and so on, according to the number of leaves of which the sheet is composed.

Origin of books.—As books are to be regarded as written records of the thoughts and transactions of mankind, their origin may be traced, in some form or other, to the invention of letters or characters, which are the representative signs of language. The materials of which books have been composed have been extremely different in different nations, and in different periods of the progress of civilization. Letters, or hieroglyphical characters, were written or engraved on tables of stone, or wood, but more frequently on the bark of trees, a substance which could be readily procured and easily prepared for the purpose; and hence the Latin word *liber*, as well as the English word book, derived from a Saxon word, and the corresponding denomination, refer to the same origin, and denote the bark of some part of a tree of which books were originally made. The materials of books were afterwards derived from the *papyrus*, a plant which is a native of Egypt, and which obviously gave its name to *paper*. The use of papyrus, it is said, was common among the ancients in the time of Alexander the Great. As the demand for books increased, more durable materials were sought for, and leather, made of the skins of goats or sheep, was employed. The use of parchment prepared from skins next followed, and, it is said, was invented at Pergamus, when the exportation of the Egyptian papyrus was prohibited. The ancient manuscripts are chiefly written on this substance, for it was not till about the 12th century that the method of manufacturing paper was known.

Attempts have been made to discover and apply to use, in the fabrication of books, materials of a still less perishable nature than any of the substances already alluded to. It has been proposed to manufacture linen from asbestos, the mineral substance

Book.

from which the famous incombustible cloth of the ancients was made, and which would be proof against fire; and in the rage, as it may be called, for the extreme durability of books, this attempt has been carried still farther by proposing an everlasting book, the whole of which was to be made of asbestos, the leaves, the cover, and the thread with which the leaves are stitched together. The writing was to be composed of letters of gold; and thus the whole would be formed of very indestructible materials.

Many changes have taken place in different countries, and at different periods, in the internal order and arrangement of letters into lines and pages. At first the letters were only divided into lines; they were afterwards separated into words, and were gradually marked with accents, and distributed by points and stops into periods, paragraphs, and chapters. In some countries the lines proceeded from the right to the left, in others, as among the northern and western nations, they ran from the left to the right; the Greeks followed both directions, alternately going in the one and returning in the other; but in the Chinese mode of writing, the lines run from top to bottom.

Scarcity of books.—Before the manufacture of paper was known, and the invention of printing, the labour and expence of multiplying books rendered them extremely scarce. On this subject Mr Warton, in his history of English poetry, has collected many curious anecdotes. The number of books, he observes, in the papal library at Rome, about the end of the seventh century, was so inconsiderable, that the pope made a formal request to the bishop of Maestricht to supply the defect from the remote parts of Germany; and about the middle of the ninth century, the abbot of Ferrieres in France sent two of his monks on a mission to the pope to beg a copy of *Cicero de Oratore* and *Quinctilian's Institutes*, because, although he was in possession of part of these books, yet no entire copy of them existed in all France. The abbot of Gemblours, with great trouble, and at an immense expence, having collected 100 volumes on divinity, and 50 volumes on profane subjects, thought himself master of a splendid library. The emperor Charlemagne, about the end of the eighth century, granted an unlimited right to the abbot and monks of Sithin for making their gloves and girdles of the skins of the deer they killed, and covers for their books. On this privilege, it is facetiously remarked, that these religious were fonder of hunting than of reading; at any rate they were obliged to hunt before they could read; and it seems probable, in such circumstances, and with such materials, the manufacture of volumes was not very prosperous. In the beginning of the tenth century, books were so scarce in Spain, that the same copy of the Bible, of St Jerome's Epistles, and some volumes of ecclesiastical offices and martyrologies, often served several different monasteries.

The constitutions framed for the regulation of the monks in England, by archbishop Lanfranc, in the year 1072, afford another proof of the scarcity of books at that period. At the beginning of Lent the librarian was ordered to deliver a book to each of the religious; a whole year was allowed for its perusal, and at the returning Lent those monks who had neglected to read the books they had received, were commanded to prostrate themselves before the abbot and supplicate his indulgence. In a catalogue of the library of the bishop of Winchester, drawn up in 1294, the whole number amounts only to seventeen books on different subjects. The bequest of a Bible in two large folio volumes, with the original annotations, certainly a valuable donation in those times, procured for the liberal donor, bishop Nicholas of Ely, the institution of a daily mass for his soul by the monks of the convent of St Swithins at Winchester, on whom it was bestowed. When a single book was bequeathed to a friend or relation, it was usually accompanied with many stipulations and restrictions; and the gift of a book to a religious house was regarded as a donation which merited eternal salvation; it was offered on the altar with great ceremony, and the most formidable anathemas were denounced against those who should dare to alienate so precious a gift. Of the formalities observed in making the bequest of a book, the following is an example. "I Philip of Repyndon, late of Lincoln, give this book, called *Peter de Aureolis*, to the new library to be built within the church of Lincoln; reserving the use and possession of it to Richard Trysely, clerk, canon, and prebendary of Milton, in fee, and to the term of his life; and afterwards to be given up and restored to the said library, or to the keepers of the same for the time being, faithfully and without delay. Written with my own hand, A. D. 1422."

The royal library of Paris, about the beginning of the fourteenth century, contained only four classics, namely a single copy of Cicero, Ovid, Lucan, and Boethius; the rest consisted of books of devotion, treatises on astrology, chiromancy, and medicine, originally composed in Arabic, and translated into Latin and French, and pandects, chronicles, and romances.

As a proof of the scarcity of books in England about the middle of the fifteenth century, the following order, which is recorded in the statutes of St Mary's college at Oxford, founded in 1446, has been quoted: "Let no scholar occupy a book in the library above one hour or two hours at most, that others be not hindered from the use of the same."

Early manuscripts, it is obvious, must always be scarce, and when they are well executed are highly prized by bibliographers; but the scarcity of printed books is owing to various causes, as the suppression of particular works on account of their immoral, irreligious, or seditious tendency,—a small impression of some books,—accidents which have happened to printing-offices and warehouses, as in cases of their being destroyed by fire,—the unfinished state of some books, and the expensive materials on which others are printed. Books which have escaped such accidents are much sought after by collectors, and, as well as first editions from ancient manuscripts, early editions of celebrated printers, such as are distinguished by peculiar characters, and such as have not been exposed to sale, bring extraordinary prices.

High prices of books.—Of the excessive prices of books in the middle ages, some curious examples are recorded. Bede's Homilies, and St Austin's Psalter, were purchased in the year 1174, by Walter, prior of St Swithins, at Winchester, for twelve measures of barley, and an embroidered pall. The countess of Anjou paid 200 sheep, five quarters of wheat, and an equal quantity of rye and millet, for a copy of the Homilies of Haimon, bishop of Halberstadt; and, about the year 1400, a copy of John of Meun's *Roman de la Rose* was sold before the palace gate at Paris for forty crowns, or L.33, 6s. 8d. But of the prevalence of bibliomania in modern times, a better proof cannot be selected than the sale of the duke of Roxburgh's library in London in the year 1812. That nobleman had been long known as an assiduous collector of the rarest editions of books. The sale extended to forty-two days, and it is supposed that the whole collection brought nearly L.30,000. As it forms a curious feature in literary history, the reader may be gratified in seeing the prices and purchasers of some of these highly valued productions.

The Festival; printed by Caxton, in two columns. L.105, bought by Lord Spencer.

The Prouffytable Boke for Mane's Soul, called the Chastysing of Godde's Chyldren; printed by Caxton. L.140, Lord Spencer.

Lyf of Saint Katherin of Senis; printed by Caxton. L.95, Mr Clarke.

Sessions Papers and Trials at the Old Bailey, from 1690 to 1803. 2 vols. in folio, and 80 vols. in 4to. L.378, Mr Read.

A Translation of Cicero on Old Age; printed by Caxton. L.115, Mr Nornaville.

The Boke of Seynt Albons; printed at St Albans, 1486; imperfect. L.147, Mr Triphook.

The Mirrour of the World; printed by Caxton in 1480. L.351, 15s. Mr Nornaville.

The Kalindayr of the Shyppers, folio; printed at Paris, 1503. L.180, Mr Nornaville.

Callimachi Hymni. Florence, 1472, 4to. L.63, Mr Payne.

A Discourse of English Poetrie, by W. Webbe, 1586, 4to. L.64, Mr Triphook.

Paradise of Daintie Devises, 4to, 1580. L.55, 13s. Mr Rice.

A Collection of Old Ballads, in 3 vols. folio. L.477, 13s. Mr Harding.

Guy Earl of Warwick, a metrical romance; printed by Copeland, 4to. L.43, 1s. Mr Heber.

Love's Martyr, or Rosalin's Complaint, by Chester, 4to, 1601. L.24, 3s. Mr Dubois.

Gower's Confessio Amantis; printed by Caxton, 1493, folio. L.336, Mr Payne.

Chaucer's Canterbury Tales, a manuscript on vellum, folio. L.357.

Chaucer's Works, by Pynson, 1526, folio. L.30, 9s. Mr Evans.

The Passetyme of Pleasure, by Stephen Hawys; printed by Wynkyn de Worde, 1517. L.81, Mr Dibdin.

The Exemple of Vertu, by Stephen Hawys; printed by Wynkyn de Worde, 1530. L.60, Mr Rice.

History of King Boccus and Sydrake. L.30, Mr Triphook.

The Complaynt of a Lover's Life, 4to, printed by Wynkyn de Worde. L.58, Mr Nornaville.

The Castell of Pleasure, 4to, printed by Wynkyn de Worde. L.58, Mr Nornaville.

The Love and Complaynte between Mars and Venus. L.60, Mr Dibdin.

Watson's translation of Brant's Ship of Fools, 4to. L.64, Mr Nornaville.

Churchyarde's Works, 2 vols. 4to. L.96, Mr Triphook.

Le Mystere de la Vengeance de Notre Seigneur J. Christ, 2 vols. folio, M. S. L.493, 10s. Mr Payne.

Shakespeare's Plays, folio, 1623. L.100, Mr Nornaville.

A Collection of Prints of Theatrical Scenes and Portraits of Performers, 8 vols. folio. L.102, 12s.

The Nice Wanton, a Comedy, 4to, 1573. L 20, 9s. 6d. Mr Nicol.

Marlow and Nash's Tragedy of Dido, 1594. L.17, 17s. Mr Heber.

Morlini Novellæ, 4to, Neapolis, 1520. L.48, Mr Triphook.

Recueil des Romans des Chevaliers de la Table Ronde, 3 vols. folio, an ancient manuscript. L.78, 15s. Mr Triphook.

Le Romant de Fier a Bras le Geant, folio, Genev. 1478. L.38, 17s. Mr Triphook.

Recueil des Histoires de Troyes, par Raoul Le Fevre, folio. L.116, 11s. Lord Spencer.

Il Decamerone di Boccacio, folio, first edition, printed at Venice by Valdarfer, 1471. L.2260, Marquis of Blandford.

The Boke of the Fayt of Armes and of Chyvalrye printed by Caxton. L.336, Mr Nornaville.

The veray trew History of Jason. L.94, 10s. Mr Ridgway.

The Recuyell of the Historyes of Troye, by Raoul Le Fevre. Caxton, 1471. L.1060, Mr Ridgway.

History of the Noble Appolyn, 4to. L.110, Mr Nornaville.

History of Blanchardyn and Eglantyne; printed by Caxton. L.215, 5s. Lord Spencer.

Delphin Classics, 67 vols. L.504, Duke of Norfolk.

The prevalence of bibliomania is not unknown in France, as will appear from the extraordinary prices of the following books at the sale of Count Macarthy's library in Paris, in 1816:

Psalmorum Codex, fol. *Mogunt.* 1457, 12,000 francs.

Psalmorum Codex, fol. *Mogunt.* 1459, 3350 francs.

G. Durandi Rationale Divinorum Officiorum, fol. *Mogunt.* 1459, 2000 francs.

Speculum Humanæ Salvationis, folio, 1320 francs, (sold in 1769 for 1600 francs.)

Historia Beatæ Mariæ Virginis, per figuras, folio, 1560 francs, (sold in 1769 for 352 francs.)

Ciceronis Officiorum, Libri III. fol. *Mogunt.* 1466, 1190 francs.

Biblia in Lingua Vulgari, 2 vols. folio, 1471, 1199 francs, (sold in 1784 for 720 francs.)

Virgilii Opera, folio, 1472, 2440 francs.

Euripidis Opera, studio Jos. Barnes, fol. *Cantab.* 1694, 1800 francs.

Xenophontis Opera, 6 vols. 8vo, large paper, Oxon. 1703, 1960 francs.

Xenophontis Cyropædia, fol. Oxon. 1728, et Xenophontis de Cyri Expeditione, Lib. VII. folio, Oxon. 1735, large paper, 2550 francs.

Thuani Historia, 7 tom. fol. bound in 14 vols. fol. London, 1733, 1225 francs.

The enormous prices of books on natural history which have issued from the French press in the present day, are worthy of being recorded as a literary curiosity. Various editions of Buffon's Natural History have appeared at Paris between the years 1799 and 1804, from L.6 to L 50; the edition by Sonnini, in 123 volumes 8vo, with coloured figures, is stated at L.100; and another, with original designs and coloured figures by the most eminent artists, in 80 volumes 18mo, is set down at the extraordinary price of L.500. Duhamel's Treatise on Trees and Shrubs, in five volumes folio, with engravings, beautifully coloured, is marked at L.150. Le Vaillant's Natural History of Parroquets is L.45; the Natural History of Birds of Paradise, Rollers, &c. by the same author, is L.150; Rousseau's Letters on Botany, large folio, with coloured engravings from the drawings of Redouté, is L.20; and one copy of the same work, with the original drawings of that celebrated artist, stands conspicuous in bibliographical history. It is set down in the catalogue of M. Bossange and Masson at L.1000.

The reader who is desirous of indulging his taste for inquiries into this department of literary history, will find it amply gratified by consulting Dibdin's *Bibliomania*, or "Book Madness," a singular production, and richly stored with amusing anecdotes.

BOOK-BINDING, is the art of sewing together the sheets of a book, for the purpose of securing them from injury, and, at the same time, of admitting the convenient perusal of their contents. The origin of book-binding, which, in some form or other, must be nearly coeval with the invention of letters and the composition of books, is ascribed to Phillatius, a learned man of Athens, who is said to have first taught the use of a kind of glue for fastening the leaves together; and for this valuable discovery a statue was erected to his memory by his grateful countrymen.

The leaves of books are put together or secured in various ways. When they are merely sewed together, the operation is called *stitching*, which is usually practised with pamphlets, and, for temporary convenience, with larger works. In *half-binding*, the edges of the leaves are generally left uncut, the back only is covered with leather, and the pasteboard sides are covered with marbled or coloured paper. Different kinds of binding are distinguished by different names. In Dutch binding, the backs of the books are of vellum; and in French binding a slip of parchment is applied over the back, between each band, and the ends are pasted on the inside of each pasteboard. This method of binding, technically called *indorsing*, is peculiar to the French binders, who are required by a particular regulation, under the sanction of a penalty, to practise it. Binding in parchment, in sheep, in calf's leather, and in Russia, Morocco, &c. by which the nature of the material with which the book is covered is designated, are familiar terms in this art.

The most ancient method of binding books in volumes was that of glueing the leaves together, and rolling them on cylindrical pieces of wood; this is called Egyptian binding, and it is now altogether disused, except in Jewish synagogues, where the books of the law are written on vellum, and sewed together, constituting one long page, which has a roller at each extremity, furnished with clasps of gold or silver. The invention of square binding, which is now generally practised, and in which the sheets are laid over each other, is ascribed to a king of Pergamus, to whom the world, it is said, is also indebted for the method of preparing parchment.

Folding, &c.—The preliminary operation in book-binding is, to fold the sheets according to the form in which they have been printed, namely, in two leaves, for folios, four for quartos, eight for octavos, &c. A folding-stick, as it is called, which is a thin slip of ivory, or bone, or hard wood, is employed for this purpose. The letters and numbers at the bottom of the pages, technically denominated signatures, direct the workmen in the proper arrangement of the sheets. The leaves being folded and disposed in the order of the signatures, are beaten with a heavy hammer on a stone, to make them smooth and solid, and they are afterwards pressed: they are then sewed in a sewing press on cords, or packthreads, or bands, at a proper distance from each other, and in a convenient number. Beginning with the first band, and proceeding to the last, the workman draws a thread through the middle of each sheet, and turns it round the bands. The number of bands, which varies according to the size of the book, is usually six for folios, and five for quartos, octavos, and the rest. When the back of the book is intended to be smooth, as is frequently the case in the binding of the present day, a saw is employed to make places for the bands, so that they are sunk in the paper. The back of the book is then glued, and the ends of the bands being opened, are scraped with a knife, for the more convenient fixing of the pasteboard sides; the back is then turned with a hammer, the book being fixed in a press between backing boards, for the purpose of making a groove for admitting the pasteboard sides; when the boards are applied, holes are made in them, through which the bands are drawn, the superfluous ends of which are cut off, and the parts are hammered smooth.

Cutting the edges, &c.—After the operations now described are completed, the book is pressed for cutting; this is performed by an instrument called a plough, to which a knife is attached; it is placed in the cutting press between two boards, one of which is even with the press for the knife to run upon, and the other rises above it for the knife to cut against; the pasteboards are then squared with a proper pair of iron shears, after which the book is ready for sprinkling, blacking, marbling, or gilding the leaves. Vermilion or sap-green is usually employed for sprinkling the leaves, which is performed with a brush of hogs bristles, the brush being held in one hand, and the hair being moved with the other.

Gilding the edges.—When the edges are intended to be gilt, it is placed in a press between two boards, and first scraped with a knife called the scraper, and then with another called the smoother, that all the scratches may be removed. When it is quite smooth

Bookbinding.

a little yellow ochre is scraped upon it, and, being moistened with a little size-water, is rubbed off with clean shavings. The gilding size is composed of white of eggs mixed with water, and well beaten together, and the leaves being moistened with a brush dipped in the size-water, the gold is laid on and dried before the fire; when it is dry it is burnished with a dog's tooth. When the leaves are blacked, they are first moistened, then rubbed with fine antimony till they are quite dry, and afterwards subjected to the operation of the burnisher, as in gilding.

Covering of books.—The skins employed in the covering of books are prepared by different processes, according to their different qualities. When the cover is of calf skin, it is moistened in water, cut to the size of the book, and the thickness of the edges pared off; the cover is then smeared over with paste, stretched over the pasteboard on the outside, and doubled over the edges within; the book is then firmly bound between two boards, the back is warmed at the fire to soften the glue, and the leather of the back is rubbed down to make it apply close; the book is then dried and uncorded, when it is washed over with a little paste and water, the edges and squares are blackened with ink, and sprinkled or marbled; the cover is then glazed twice with white of egg, filleted plain or with gold, and, last of all, polished with an iron passed hot over the glazed cover. When the book is titled on the back, a piece of Morocco leather, of such colour as may be required, is pasted between the first and second band, to receive the title in gold letters.

Gilding the back and cover.—In common binding, the edges of the cover and the backs of books only are gilt; but books are sometimes splendidly decorated with various figures in gold. Flowers, roses, coats of arms, and other ornaments, are made with gilding instruments engraved in relievo, either on the points, puncheons, as in the case of letters, stars, or small figures, or a round small cylinder of brass, and the like. Those parts of the leather on which the gold is to be applied, are glazed three or four times with size-water, by means of a spunge; when they are nearly dry they are slightly oiled, the pieces of gold leaf are laid on, and the tools are either pressed with the hand, or the cylinders are rolled along the places to be gilt, both instruments being a little heated. The gilding being finished, the redundant gold is rubbed off, and the whole is polished. Gilding on rough leather is performed by means of resin dried and powdered, instead of whites of eggs; the gold leaf, cut to a proper size, is placed on a hot slightly-oiled stamp, and pressed down, and as the resin melts only in those parts where the hot stamp is applied, the other parts of the leather remain as at first.

Improved methods of binding books have been proposed of late years, and the advantages of the improvements have been secured to their inventors by patent; one of these, by Messrs Williams of London, is applied to all kinds of books; and another, by Mr Palmer, is chiefly useful for merchants acccount books. For an account of both, see *Repertory of Arts*, Vol. XIV.

BOOK-KEEPING.

Definition.

Book-keeping is the art of keeping merchants accounts,—the art of recording the transactions of trade, in such a manner that the merchant may be able, at any time, to determine with facility the exact state of his affairs. The mode of doing this being perfectly arbitrary, various methods of book-keeping have been used. We shall here endeavour to explain the principles of what has been termed the *Italian Method*, or *the Method by Double Entry*, as it is the method most universally adopted.

Chap. I. Of the Books.

Object of

The great object of book-keeping is to discover, at any time, what the merchant is worth, and there are two ways in which this may obviously be accomplished, namely, 1*st*, By collecting into one sum the whole amount of his property, and deducting from it the whole amount of his debts; or, 2*dly*, Knowing the amount of his property at any former period, as, for example, at the time he begins business, by adding to or deducting from it the amount of his gain or loss since that time. Now, it has been found necessary in book-keeping to use both these methods, in order that, by arriving at the same conclusion in different ways, we may be the more assured of the accuracy of the result, or, in case of any inaccuracy, that we may perceive the extent of the errors that have been committed.

In every mercantile concern, where the merchant is continually buying and selling, receiving some goods and delivering others in return, receiving from some people on credit, and delivering on credit to others, his property must consist, in a great measure, of the value of the goods delivered on credit, and his debts of the value of the goods received. The amount of his profit or loss also, in the whole of his transactions, must be equal to the total sum of the profits or losses that have arisen by his dealings in each separate article, and these again depend evidently upon the prices at which he buys, and the prices at which he sells the articles. In recording these various transactions, therefore, with the view of readily striking the balance between his debts and his credits, his gains and his losses, it is necessary to adopt a pecu-

Waste-book. liar arrangement. It is necessary, 1*st*, That the *opposite* transactions of giving away and receiving be kept quite distinct from each other; 2*dly*, It is necessary, with the view of ascertaining the state of the merchant's accounts with other people, that the transactions with different *persons* be kept distinct from each other; and, 3*dly*, With the view of shewing the gain or loss in each article, that the transactions in different *articles* be kept distinct from each other.

Leger.—There is, accordingly, in the Italian, as in every other method of book-keeping, a principal book, termed *the Leger*, to the formation of which the other books are only subservient, which contains a complete state of the merchant's affairs, and in which all his transactions are recorded, according to the above arrangement.

Waste-Book.—But in order to secure the insertion of every transaction without exception, it is quite necessary that each of them be entered in the books at the moment, if possible, it takes place; and as it would be very inconvenient, in the hurry of business, to be searching in the leger for the place where every transaction, according to its nature, ought to be inserted, it has been found necessary to make use of another book, termed the *Waste-book*, where each transaction, of whatever description, is entered exactly as it arises, and from whence it is transferred, at leisure, to its proper place in the leger.

Journal.—To make this transference also with greater expedition and accuracy, it has been found necessary to use a third book, termed the *Journal*. The construction of these books we shall now more particularly describe.

Chap. II. Of the Waste-Book.

From what has been said of the nature of this book, its construction will be easily understood. It begins, as in waste-book A, with a full account of the merchant's property, an inventory of every article in his possession, and a list of all the debts due to him, and of all the claims against him, and then proceeds with an account of every transaction that occurs, expressing it in short but intelligible language. It is ruled, as in the example below, from top to bottom, with three columns to the right for *L. s. d.* and one to the left for a margin, the space between these columns being occupied with the dates and narratives of the transactions; the date is written at full length, and in large characters, as the head-line of each page, and in the middle of that line,—ink lines being drawn on each side of it to the margin line on the left, and to the money lines on the right. In dating the transactions of the following days, the day only is written between the opposite ink lines, the month not being repeated in the same page. Lastly, the transactions of the same day are either separated from each other by a line drawn wholly across the page, from the margin to the money columns, or the date is repeated.

Leger.

EXAMPLE.

WASTE-BOOK.

	Edinburgh, January 1. 1816.	L.	s.	d.
	Bought for ready money, 400 yards shaloon, at 1s. 3d.	25	0	0
	3			
	Bought of J. Innes, 18 hhds. wine at L.30,	540	0	0
	3			
	Received of David Jackson, L.100 lent to him, with interest on the same,	104	0	0
	Sold William Keith, 1 pipe of port wine,	90	0	0
	6			
	Bartered with Robert Stevens, 1 pipe of port wine for $1\frac{1}{2}$ ton of madder at L.3 per cwt.	90	0	0

Chap. III. Of the Leger.

Sect. I. *Of the opposite sides of the Leger.*

In the leger, as we have already observed, the transactions entered in the waste-book are arranged in distinct classes.

In the *first* place, they are all arranged according to the opposite relations of buying and selling—of things received and of things delivered. It has therefore been agreed to allot the opposite pages of the leger for inserting the values of articles of these opposite kinds; and, in numbering the pages, these two opposite ones are considered as one folio.

Sect. II. *Of Personal Accounts.*

Secondly, The transactions of the waste-book are arranged in relation to the *persons* with whom they have taken place; the dealings with each person or company being all collected together under one point of view, and under the title of an *account*. These accounts are termed *personal* accounts, and one of them is opened with every person with whom there are any dealings; a certain space is allotted in the leger for receiving this account, and when that space is filled up the account is transferred to another page, where another space is allotted to it.

The object of a personal account is to shew how much the merchant owes that person, or how much the latter owes him; and as this quantity, in every particular transaction, is evidently the difference between the value of what he gives that person and the value of what he receives from him, so in the whole of their transactions with each other it is the difference between the sum total of the values given and the sum total of the values received. In transferring, therefore, the entries of the waste-book to the leger, with the view of ascertaining these sums, we have only to set down carefully, in every personal account, the value of the articles received by each transaction, on that side of the leger which has been allotted to articles bought, and the value of the

Personal Accounts.

articles given by each transaction on the opposite side of the leger, and in the same account; money columns being drawn on the opposite pages to receive these opposite values.

In this manner the state of accounts with Thomas Anderson, according to the transactions narrated in waste-book A, are easily ascertained. Thus,

Goods delivered or sold on credit.		*Goods received or bought on credit.*	
Jan. 15. Paper	L.18 0 0	Mar. 24. Paid in by him to the Royal bank, on	L.40 0 0
Feb. 1. Salt, yarn, and iron, amounting in all to	28 0 5	Amount of goods delivered	73 0 0
Ap. 12. Train oil	27 0 0		
	73 0 5	Difference—the sum due by T. Anderson	L.33 0 0

In forming this balance, it is evidently of no consequence on which of the pages of the leger these opposite quantities are inserted. But it has been agreed to enter goods bought on the left hand page, and goods sold on the opposite. A peculiar form has also been adopted in these entries, as will be seen in Thomas Anderson's account in leger A. The left-hand page has been called the *debtor*, or *Dr.* and the right the *creditor Cr.* or *contra* side of the leger or of the account. In the former is written, at the head of the account, the name of the person in large characters; in the same line of the page the word *Dr.;* and the titles of the articles are preceded by the word *to*, so that the whole reads thus; *Thomas Anderson, Dr. to paper, to oil, to sundries*, and so on, which means nothing more than that these things have been delivered to Thomas Anderson, and that he is accountable for them to the deliverer. On the opposite side of the account, again, which contains articles received from the person, the words *Contra Cr.* are written in a line, with the name and the articles preceded by the word *by ;* so that the whole reads thus, *Contra Cr.* that is to say, *Thomas Anderson, Contra Cr. By Royal bank paid in by him,—By cash*, or *by* any article received. It is doubtful if this technical mode of entering the accounts has any, and at all events it is not necessary that it should have any meaning, further than indicating the opposite sides of the leger—the opposite relations of buying on credit and selling on credit; and though the words *to* and *by* are universally prefixed to the narratives, these opposite relations might equally well have been indicated by the simple terms *Dr.* and *Cr.* which would then have been of the same nature with the signs *plus, minus*, &c. in arithmetic.

But at the time of opening the books, there usually remain unsettled a number of balances of the personal accounts of the former books; these constitute so many debts due to the merchant on the one hand, or by him on the other. Being accordingly all entered in the inventory with which the waste-book begins, they are transferred from it to the accounts of the same persons in the new leger; and as they are evidently of the same nature, the debts due to the merchant as goods sold, and the debts due by him as goods bought, they are entered on the same sides of the accounts respectively, the former on the Dr. or left-hand side, and the latter on the Cr.

Real Accounts.

Sect. III. *Of Real Accounts.*

Thirdly, The transactions in the waste-book are arranged in the leger relatively to the *articles* about which they have taken place, such as goods of all kinds, houses, lands, ships, shares in public companies, and the like; those concerning each article being formed into a separate account. These accounts are called *real accounts*, and their object is to exhibit the gain or loss that has arisen by the dealings in any particular article; and also, by shewing how every article has been disposed of, to satisfy the merchant that nothing has been lost, or to point out the quantity amissing.

If A, for example, buys 100 qrs. of wheat at 80s. a quarter, and sells it again at 90s. he will evidently gain L.50; but if he again buys 100 qrs. at 90s. and is obliged to sell it when the price has fallen to 75s. he will lose L.75 by the latter transaction; but in the two transactions together he will only lose L.25. One object of every real account, therefore, is to shew the total quantity of gain or loss upon a variety of separate transactions in the article to which it relates; and as the gain or loss on any particular transaction is evidently the difference between the price at which we buy (the *prime cost* as it is termed by retail dealers) and the price at which we sell, so the total gain or loss is the difference between the total sum of the prices at which we buy, and the total sum of the prices at which we sell. In transferring, therefore, to the leger the transactions concerning articles, with the view of striking the balance of profit or loss, it is only necessary to set down the value of every article bought on one side of the account, and the value of every article sold on the opposite; by adding these opposite money columns into two sums, and taking the difference between them, we obtain the total gain or loss upon the article in question, viz. the total gain, if the value of articles sold exceeds that of the articles bought, and the total loss if the contrary. In this manner the profit on the dealings in iron, for example, is obtained, as they are narrated in the waste-book A. Thus,

Articles bought.		*Articles sold.*	
Jan. 13. Bought of W. Johnston 320 stones at 3s. 4d.	L.53 6 8	Feb. 1. Sold Tho. Anderson, 100 st. at 3s. 4½d.	L.16 17 6
		Mar. 28. Robertson & Ritchie, 150 at 3s. 7d.	26 17 6
		April 1. Sold for ready money 70 st. at 3s. 6½d.	12 7 11
	L.53 6 8		L.56 2 11
Articles sold	56 2 11		
Difference, the amount of gain	2 15 3		

Real Accounts.

In the above examples we have supposed the goods to have been all bought and all sold; but this is seldom the case, as there is generally a quantity on hand at the time of opening the books, and a quantity unsold at the time of striking the balance; the gain or loss, however, is obtained upon the same principle. A, for example, has on hand at the time of beginning business 100 quarters of wheat, the selling price being then 60s. and at balancing the accounts finds that 50 quarters had been sold at 80s. and 50 at 70s. producing in all L.375. Now, the value of the wheat on hand at opening the books was evidently L.300, the sum for which it could have been then sold, but it was actually sold for L.375, and thus produced a gain of L.75, the difference between these two values.

On the other hand, if none of the goods have been sold, but all remain on hand at the time of balancing, it is clear that the gain or loss on these goods would be the difference between the sum of the prices at which they have been bought, and the price for which they would then sell, that being their value at the time. If A, in the above example had only sold 50 quarters at 80s. leaving on hand 50 quarters at the time of balancing, the price being then 70s. it is evident that his gain on the transactions would be still L.75, for if he did not sell the 50 quarters at 70s. he might have sold them, and that was their value at the time. It appears then, that, in every case, the gain or loss is the difference between two quantities which stand on the opposite sides of the leger, viz.

1*st*, When the goods are all on hand at the time of opening the books, and all sold during their currency, it is the difference between

The price at which they would sell at opening the books, } and { The sum of the prices at which they have been sold.

2*dly*, When the goods are all bought and all sold during the currency of the books, it is the difference between

The sum of the prices at which they have been bought, } and { The sum of the prices at which they have been sold.

3*dly*, When the goods are all bought during the currency of the books, and all remain on hand at the time of balancing, it is the difference between

The sum of the prices at which they have been bought } and { The price at which they would then sell.

Now, every case that can possibly happen is made up of these three in different proportions. In general, therefore, and universally, the gain or loss is obtained by adding up, on one side of the leger, the market-price of the goods on hand at opening the books, together with the prices of all that are bought during their currency, and, on the opposite side, the prices of all that are sold during the currency of the books, and the market-price of what remain on hand at balancing; and hence the general rule, to *enter, at their market-price, goods on hand at opening the books on the same side of the leger with goods bought, and goods on hand at balancing on the same side with goods sold.*

Charges on goods.—Any charges on goods, such as carriage, freight, postage, or other incidental expences, tend evidently to diminish the profit which would arise from the sale of them. Thus A buys 100 quarters of wheat at 60s. and, after keeping it a year, sells it at 70s. thus gains, if there were no charges, L.50; but L.5 is paid for granary rent, and L.2 for the interest of money, L.7 therefore must be deducted from the price sold at before it can shew the nett gains by its excess above the price bought at. As in every particular transaction, therefore, all charges must be deducted from the prices of goods sold, so in a variety of transactions all the charges are entered as they arise on the opposite side of the leger, and, being all added up along with goods bought, are all deducted along with them, at one operation from the total value of goods sold.

Advantages.—Any immediate advantage, on the other hand, is entered upon the same principle on the opposite side of the leger along with articles sold.

Quantity columns.—The next object of real accounts is to indicate any deficiency, or the contrary, that may have arisen in any of the articles. This is done by setting down their quantities, that is, their weight, measure, or the like, in an inner column, as well as their values in the outer money column, as in the above example. Thus,

	Bought	Stones.					*Sold*	Stones.			
1816. Jan. 5.	Of Mr Johnston, iron at 3s. 4d.	320	L.53	6	8	Feb. 1.	Thos. Anderson, at 3s. 4½d.	100	L.16	17	6
						Mar. 28.	Robertson and Ritchie, at 3s. 7d.	150	26	17	6
						Apr. 1.	For ready money at 3s. 6½d.	70	12	7	11
		320	L.53	6	8			320	L.56	2	11

The quantities bought being thus equal to the quantities sold, shews clearly that the whole stock has been disposed with nothing lost or missing.

But it frequently happens that the quantities bought, when they come to be minutely examined, turn out sometimes more, but most frequently less, than what they have been entered for, either from erroneous measurements or other causes, on the one hand, or from tear and wear, leakage, or waste of any description, on the other; and these inner columns of quantities, therefore, have the advantage of indicating this excess or defect. For, if there be no error in the entries, in the measurements, or in any other way, the quantities on hand at opening the books, together with the quantities bought during their currency, must be exactly equal to the quantities sold

Real Accounts.

together with the quantities on hand at balancing; and when this equality, therefore, does not take place, it shews clearly an error, which, if not in the entries, must be in the quantities themselves. If the quantity bought and on hand at opening exceeds the quantity sold and on hand at balancing, as in the account of oatmeal in leger A, it shews clearly that there has been an error in the measurement, or that so much has been wasted, lost, or is missing, and the excess is termed *income*, or *amissing*. If, on the other hand, the latter quantity exceeds the former, it shews that the quantities have turned out more than what they were entered for, and, therefore, is entitled *outcome*. But in both cases, as the values of these excesses have been already entered in the money columns, their quantities only are set down in the inner columns, under the titles of income and outcome.

Particular accounts.—We may now mention a few accounts in particular. From what has been said the reader will easily see the reasons of the different entries; and thus guided by the general, and really most obvious principles, on which all accounts are constructed, will have no difficulty with any more complex case that may occur. The general rule is, that every real account must contain, *on the one hand*, 1*st*, *The quantity of the article on hand at the time of opening the books, and its value at the market price;* 2*dly*, *The quantities and values of all that is bought;* and, 3*dly*, *All disadvantages, such as incidental expences:* And, on the other, 1*st*, *The quantities and values sold*; 2*dly*, *The quantity on hand at balancing, and its value at the market-price;* and, 3*dly*, *All advantages, such as drawbacks, bounties, &c.*

Accounts of houses and lands contain, on the one side, the value of the property at the time of opening the books, together with the amount of all the money laid out for repairs, taxes, improvements, or any other species of expence, and also the value of any other property that may have been annexed to it by purchase; on the opposite side, the amount of all money received for rents, for the sale of any part of the produce, or of any part of the property, and also the value of the property at the time of balancing.

In the same manner accounts of ships contain, on the one side, the value of the vessel at opening the books, together with the expences for repairs, for shore-dues and other taxes, for mens' wages, or for any other thing; and, on the opposite side, the amount of all freights or other advantages received.

Accounts of property in the funds, or in public or private companies, contain the value of the share at opening the books, with all the sums paid in, on the one side,—and on the opposite, the amount of all the dividends received.

The account of ready money, termed the *Cash account*, of which the balance shews merely what is on hand or missing, contains the quantity on hand at opening the books, and all sums received, on the one hand,—and, on the other, all sums paid, together with the quantity on hand at balancing. These opposite columns should be alike, else some money has been received or given away which is not accounted for; and thus any loss or incidental gain is indicated.

Besides these and similar accounts, it is necessary to open in the leger an account termed the *Stock account*, in order to exhibit at the time of opening the books the nett amount of the merchant's property. It contains, therefore, on one side, the amount of all his debts, and of all claims upon his property, and on the opposite side the amount of ready money, goods, and property of every kind, together with all his claims upon other people. The balance shews the extent of his stock, or, in case of bankruptcy, the excess of his debts above his funds.

Real Accounts.

Lastly. There is opened in the leger an account termed the *Profit and Loss account*, in which are collected all the articles of gain or loss, in order to shew the general balance upon the whole. It contains, on the one hand, every article of gain which arises during the currency of the books, and is not entered in the other accounts, such as money received by legacy, by commission, insurance, or the like; and, on the other, every article of loss, such as goods destroyed, money paid for interest, for insurance, for warehouse rent, or other expences. At balancing the books also, the total gain or loss arising from all the different accounts is entered on this account, and the balance exhibits the result of the whole. This account, however, contains only the abstract of various other accounts of profit and loss, the details of which it has been found convenient to keep by themselves, and even, in extensive business, to keep in separate books. The following are the principal of these accounts.

The account of *Charges of merchandize*, which contains on the one side all charges incurred in business which have not been entered in the other accounts; and if any should be afterwards so entered, they are not erased from this account, but, what has the same effect, entered again on the opposite side.

The account of Proper expences, which contains on the one side all the money, or any other thing, withdrawn from the business for private use; and there is seldom any thing on the opposite side.

The interest account, the commission account, the insurance account, the account of loss by bad debts, the account of abatements, and various others, are all of the same kind. The account of stock and of profit and loss are sometimes termed fictitious accounts.

Sect. IV. *On Double Entries.*

Such are the principal accounts in the leger. Now, in all these accounts, as well as in the case of personal accounts already noticed, it is obviously of no consequence, in obtaining the balances, on which of the two pages of the leger the different articles be entered, provided those of the same kind be kept on the same page,—articles bought, for example, on one page, and articles sold on the other. Let us see, then, which of them is to be preferred on other accounts. This is a matter of some importance in book-keeping, as on it depends a method of proving the accuracy of the accounts. We may first consider the transactions of buying and selling. In every case of this kind there is the *thing* bought or sold, and the *person* who buys or sells it; and in the above arrangement of leger accounts, *the value*, as we have seen, is entered in the account of the former as well

Double Entries.

as in the account of the latter,—is entered both in the *real* and in the *personal* account to which it relates. In every case of this kind, therefore, the very same quantity is entered twice in the leger.

Now it has been agreed, as we have shewn, to enter the values of articles bought on the *right* hand, or Cr. side, of personal accounts, and the values of articles sold on the left. If in real accounts, therefore, we should enter the values of articles bought, not on the right, but on the *left* hand side of the leger, and also the values of articles sold on the *right*, it would then happen that the value of each article of this kind, without exception, would be entered once on the right of the leger and once on the left. The total sum of the money columns, therefore, of all the right-hand pages, would exactly equal the total sum of the money columns of all the left; and the existence of this equality would prove the accuracy of the entries, while the smallest inequality would indicate with certainty a proportional degree of error.

This arrangement has accordingly been universally adopted in the Italian book-keeping, which has since received the name of the *Double Entry* method. The values of articles bought, which have been agreed to be entered on the *right* of personal accounts, have been also agreed to be invariably entered on the *left* of real accounts; and the terms Dr. and Cr. have been also extended to the latter, the left-hand page being still termed the Dr. and the right-hand the Cr. side of the account. It must not be imagined, however, that these terms have any meaning, farther than to designate the opposite sides of the account. In personal accounts they may perhaps have some analogy to their ordinary acceptation, but in real accounts they have none; and the signs *plus* and *minus* of arithmetic would have equally answered the purpose.

Many articles of the leger, however, are neither bought nor sold from the time of opening to the time of closing the books, and many are not bought or sold at all. But in whatever account any article of this description be entered, there is always, from the nature of leger accounts, another in which it must also be inserted. Thus, goods or money on hand at opening the books, houses, lands, &c. which are entered in real accounts for the purpose of shewing the balance of profit or loss, &c. must also be entered in the account of stock, in order to determine what the merchant is worth. In the same manner, money received or paid must be entered both in the cash account and in the account of the person from whom or to whom, or of the thing on account of which it is received is paid; every article of gain or loss also must be entered on the account of the article, as well as in the account of profit and loss. Thus, in every other transaction, as well as in that of buying and selling, there is also invariably a double entry in the leger. Now, as it is in all cases a matter of perfect indifference, as to the formation of a balance, on which of the two sides of an account all the Dr. and Cr. articles be placed, it has been agreed, as in the case of articles bought and sold, to enter the articles upon the respective sides of the leger, in such a manner that all the double entries may be equally divided between its opposite pages. The sums of the whole of the opposite money columns being in that case exactly alike, the existence of this equality serves to prove the accuracy of the accounts; and as any inequality indicates with certainty an error, we thus obtain a very convenient check upon those mistakes which are so apt to arise in every system of keeping accounts.

Balancing Accounts.

Sect. V. *On the Balancing the Accounts and Closing the Books.*

To enter every article, in this manner, upon the proper side of its account, is the most difficult part of book-keeping; and the Journal has been contrived to facilitate this operation, to smooth the way, as it were, from the waste-book to the leger. Before explaining, however, more particularly the nature of the journal, we shall shew how to balance the accounts in the leger, which may be sufficiently understood without regard to the sides on which the Drs. and Crs. of each account ought to be entered.

Personal accounts.—Whenever accounts are settled with any person, his account in the leger to that period is finished or closed, and a new one opened for future transactions. When the sums of the opposite sides of the account are equal, it shews that the parties are clear with each other, or that there is nothing due on either side. In this case, the account balances itself; it is closed by setting down the equal sums of the opposite money columns opposite to each other, and the new account begins with the first subsequent transaction that occurs. But when the sums of the opposite sides are unequal, the difference shews how much one party is indebted to the other; the account is balanced by adding this difference to the smallest side in order to make it equal or *balance* the other,—and this balance being carried forward, forms the first article of the new account. Thus in A's account with the Royal Bank, the sums of the Dr. and Cr. sides are L.190 and L.400 respectively; the difference between them, L.210, is what A owes the Royal Bank. The account is closed thus,

Royal Bank,	*Dr.*	*Contra,*	*Cr.*
To cash paid	L.190	By cash received	L.400
To balance	210		
	400		400

And the new account begins thus,

Royal Bank,	*Dr.*	*Contra,*	*Cr.*
		By balance of former account	L.210

Real accounts.—Real accounts are balanced in the same manner as personal: When no part of the article remains on hand, if the opposite columns of quantities, and also the opposite money columns, be equal, the account balances itself,—there has been neither gain nor loss, neither outcome nor income,—and it is closed by setting down the equal sums opposite to each other. If part of the article be on hand, it is added, as we have seen, to the creditor side of the account, the quantity in the quantity column, and the market-price in the money column. If the opposite quantity columns be then unequal, the difference is outcome, or income, and is added, under its proper title, to the smallest quantity column of the account. If the opposite money columns be unequal, the difference is the gain or loss, and is added to the smallest money column. The sums of the opposite columns being then equal, the account balances; it is closed by setting down the equal sums opposite to each other, and the new account begins with the quantity on hand. The manner of thus closing the account, and entering the different quantities, will appear in the example of oatmeal, leger A.

Oatmeal,	Bolls	*Dr.*			*Contra,*	Bolls	*Cr.*		
The sum of the articles on this side is - - -	130	L.133	13	0	Sum of articles on this side	114	L.143	9	0
To profit and loss for gain		33	1	0	By balance on hand at 30s.	$15\frac{1}{2}$	23	5	0
					Missing - - - - - - -	$\frac{1}{2}$			
	130	L.166	14	0		130	L.166	14	0

The new account begins thus:—

Oatmeal,	Bolls	*Dr.*			*Contra,*	Bolls			
To balance on hand by former account, at 30s. -	$15\frac{1}{2}$	L.23	5	0					

In the same manner, the cash-account is balanced by adding the difference, if any, between the opposite money columns, to that which is the least;—this difference shews the account of cash on hand, and its agreement with what is actually on hand serves to prove the accuracy of the account.

General balance.—Few of the real, or even of the personal accounts, however, are closed until the time of forming the general balance of the books, which it is usual among merchants to do once a-year. This operation is merely the collection of all the scattered balances into one general result, in order that, by finding the total gain or loss on the whole of the transactions, and also the total amount of debts owing to or by him, the merchant may be thus enabled to determine the exact amount of his property. The first thing to be done in balancing the books, after settling all the small accounts and charges in the business, and taking an exact inventory of the goods on hand at their market-prices, is to prove the accuracy of the leger-entries, by forming what is called *the trial balance.* This is done by adding into one sum the whole of the Dr. money columns, and into another the whole of the Cr. If the two sums be equal, the accounts are correct; if unequal, they must be carefully examined until the error be discovered. The next object is to add together all the balances. Those of personal accounts are collected in a separate paper, termed the *balance-sheet,*—the balances due to the merchant on one side, and by him on the opposite. The balance-sheet contains, also from the inventory, the value of every article of property on hand, including cash. The balances of real accounts are also collected on a separate paper, termed the *profit and loss sheet,* those of profit on one side, and of loss on the opposite. The difference between the opposite sides of the balance-sheet then shews evidently what the merchant is worth. The difference between the opposite sides of the profit and loss sheet is the total gain or loss; and this being added or taken from the nett amount of his property at the time of opening the books, shews also what the merchant is worth. When the two results, thus obtained by methods so totally independent of each other, agree together, it affords the strongest proof of the accuracy of the accounts. If they do not agree, it shews that some error has been committed; and the accounts must be all re-examined in order to discover it, or at any rate to bring the two results as near to each other as possible. In an extensive business, it is seldom that they come out exactly alike; but as the difference between them is always the extreme limit of the error, it forms a very convenient measure of the accuracy of the books; and, therefore, when this difference has, by repeated examinations, been reduced to a trifling amount, the error is neglected, and the balance is effected by making profit and loss Dr. or Cr. for the amount.

Closing the books.—Having thus ascertained the exact state of the business as nearly as circumstances will admit, or as there is any occasion for, the next object is to close all the accounts. Real and personal accounts are closed in the manner already stated; and there only remains, after these, the accounts of stock and of profit and loss. The stock account, as we have seen, contains, on one side, the property of the merchant, or the debts due him, and on the other the debts which he owes. By adding to, or taking from the former the nett gain or loss, and adding to the latter the nett stock at the time of closing the books, the opposite sides become equal, and the account is balanced. Thus from leger A.

Stock, *Dr.*				*Contra,* *Cr.*			
To Royal Bank, per account	L.250	0	0	By sundries	L.973	0	0
To balance account for nett stock	735	13	1	By profit and loss for nett gain	12	13	1
	L.985	13	1		L.985	13	1

The reason of this is obvious; for L.973, being the amount of property and debts due, just exceeds the nett stock at opening the books by L.250, the debts then owing. By adding the gain L.12, 13s. 1d. we obtain L.985, 13s. 1d. the nett stock at balancing, together with the same L.250; by adding, therefore, the nett stock at balancing to L.250, it is clear that we obtain the same quantity, L.985, 13s. 1d.

To the profit and loss account in the leger is car-

Journal. ried the amount of the profit and loss sheet; the difference between the sums of the Dr. and Cr. sides is then the total gain or loss; and being added to the smallest side, the account balances, and is closed, like the rest, by setting the opposite sums opposite to each other. In this manner, the whole of the leger accounts are closed, and every thing is prepared for opening a new series. We have now only to explain the forms and rules for entries in the journal.

Chap. IV. Of the Journal.

The journal is either kept separately, or, what is far more convenient, it forms, along with the waste-book, the opposite pages of the same book. It is ruled and dated in the same manner as the waste-book. The entries, as they refer to the same transactions, are made in the same order, and, if upon opposite pages, exactly opposite each other; and on the left-hand margin are written, for the sake of reference, the folios of the leger to which the articles are carried.

Form of entries.—The only object of the journal is to shew, upon inspection, in what account, and on what side of the account or of the leger the value of each article should be placed. The account is indicated by writing its title, that is to say, the name of the person or thing to which it relates, and the side of the account is marked by writing for the Dr. side the word Dr. after the title, and for the Cr. side the word *to* before it. Thus, if the value of an article were to be entered on the Dr. side of A's account, and on the Cr. side of some real account, suppose cash, the journal *entry*, as it is termed, would run thus, *A. Dr. to cash*; then follows a short account of the transaction, called *the narrative*, but which may be omitted if the journal occupies the opposite page with the waste-book, as the narrative of the latter will then be sufficient. In the same manner, the transaction in waste-book A, of January 3, viz. Sold James Spiers 30 bolls of oatmeal at 20s. 6d. is thus *posted*, as it is termed, into the journal. *J. Spiers Dr. to Oatmeal*, sold him 30 bolls at 20s. 6d.; and the meaning of this journal post is, that the value of the meal must be entered on the Dr. side of J. Spier's account, and the Cr. of the account of oatmeal. When there are more Drs. and Crs. than one, the entry in the journal is termed a *complex post*. Thus:

Jan. 13. Bought of William Johnston, merchant, Leith,

200 bush. salt, at 1s. 8d.	L.16 13 4	
320 stones of iron, at 3s. 4d.	53 6 8	
		L.70 0 0

This transaction is either entered thus:

Salt Dr. to Wm. Johnston for
200 bush. at 1s. 8d. L.16 13 4

Iron Dr. to Wm. Johnston for
320 st. at 3s. 4d. L.53 6 8

Or thus, at once, by uniting the two or more Drs. under the term *sundries*:

Sundries Dr. to Wm. Johnston.

Salt for 200 bush. at 1s. 8d.	L.16 13 4	
Iron for 320 stones at 3s. 4d.	53 6 8	
		L.70 0 0

and in this form there is only one entry on Wm. Johnston's account.

Nature of entries.—Such is the method of indicating any account whatever, and any side of that account; but the great thing is to be able to decide, with facility, from the nature of the transaction in the waste-book, the particular account, and, what is most difficult, the proper side of that account on which the value of the article should be placed. As the latter depends entirely upon the conventional arrangement of leger accounts, which we have already described, and of which the object is to obtain a trial balance in the leger, it is only by considering the nature of this arrangement that any general rules for these journal entries can be drawn. Journal.

The transactions of trade which are entered in the waste-book relate,

1st, To things received into, or delivered out of the merchant's possession, and to the persons from whom they have been received, or to whom delivered.

2d, To things on hand at opening the books.

In order to deduce rules for each of these cases, we must consider the nature of the accounts already described. In regard to the first case, we have seen that *personal* and *real* accounts contain, on the one hand, things received, and, on the other, things delivered; and that, as it has been agreed in personal accounts to enter things received on the Cr. and things delivered on the Dr. side, real accounts must therefore contain, in order to obtain a trial balance, things received, not on the Cr. but on the Dr. and things delivered on the Cr.

In the *stock account* there are no entries during the currency of the books; none, therefore, either of things received or delivered. *The profit and loss* account contains articles of gain or loss, which must clearly consist of things received and of things delivered. Each article is also entered in some real account, and as the latter contains things delivered on the Dr. and things received on the Cr. it is evident that, according to the arrangement which divides the double entries equally between the opposite pages of the leger, the profit and loss account must contain things received, that is, articles of gain on the Dr. and things delivered or articles of loss in the Cr.

The nature of the transactions indicates at once the *particular* account in which the things received or delivered must be entered. If received on credit, they are entered in some real and in some personal account—in the account of the thing received, and of the person from whom received,—on the Dr. of the former therefore, and on the Cr. of the latter. If received from one person on account of another, or on account of some thing, as the rent of a house, or the like, they are entered in the account of the thing received, and of the person or thing on whose account they have been received,—on the Dr. of the former, therefore, and on the Cr. of the latter. If received in exchange for other things, they are entered on the Dr. of the things received, and on the Cr. of the things delivered, or given in exchange; if on account of gain or loss, they are entered in the account of the thing received, and in the account of profit and loss,—on the Dr. of the former, therefore, and the Cr. of the latter. Upon the whole, therefore, and adopting the form for journal entries already described, the following rule for things received may be drawn.

Journal.

The thing received is	Dr.	To the person from whom it is received. To the person or thing on whose account it is received. To the thing given for it. To profit and loss.

The same rule applies in a reverse order to things delivered, thus:

The person to whom the thing is delivered. The person or thing on whose account it is delivered. The thing received for it; or, profit and loss.	Drs.	To the thing delivered.

The application of these rules will be evident from the following examples.

1. Bought of William Maclaren 100 qrs. of wheat at 80s. L.400. Here wheat being the thing received, and William Maclaren the person from whom it is received, the entry is,
   Wheat Dr. to William Maclaren.
2. Received from Alexander Beattie in full, L.60. The entry is here evidently,
   Cash Dr. to Alexander Beattie.
3. Bought for ready money, 20 gallons rum at 20s. L.20. Here *rum*, (the thing received,) is *Dr. to Cash*, (the thing delivered.) In the same manner in the following:
   Bartered 10 doz. port wine at 30s. for 15 gallons rum at 20s.; the entry is,
   Rum Dr. to Port Wine.
4. Paid for repairs to my house in Queen's Street, L.30. Here *House in Queen's Street*, (on account of which the thing is delivered,) is *Dr. to Cash*, (the thing delivered.) In the same manner are entered the following:
   Paid for shop rent L.10.
   Profit and Loss Dr. to Cash paid for shop rent.
   Received rent of house in Queen's Street, L.70.
   Cash Dr. to house in Queen's Street, (the thing on whose account the money is received.)
   Received 100 bolls of oatmeal, being the rent of my farm of Braehead,
   Oatmeal Dr. to farm of Braehead.
   Taken for the use of my house, 1 doz. port wine,
   Profit and Loss Dr. to Port Wine, (the thing delivered, or withdrawn from the business.)
   Received in a legacy L.100.
   Cash Dr. to Profit and Loss.

In the above transactions, things received or delivered on credit are entered in the accounts of the things; but in many cases debts are incurred for things which have no accounts in the leger,—as for services in the business, expences for articles, such as houses, ships, &c. interest of money, insurance, or the like, on the latter of which also debts become due to the merchant. These, however, are entered in the same manner, only substituting for things received the persons indebted to the merchant on account of them, and for things delivered the persons to whom the value is due, according to the following rules:

The person who owes, or is accountable for the thing, is	Dr.	To the thing given. To the person or thing on whose account it is given, or to profit and loss.
The thing received. The person or thing on whose account it is received, or profit & loss,	Drs.	To the person to whom the value is due.

Thus the following are entered:

William Burnet owes me rent of my house in Princes Street—
William Burnet, Dr. to House in Princes Street.
David Dobson owes me L.10 for interest of L.200—
David Dobson, Dr. to Profit and Loss.
Due William Davidson, my clerk, for wages, L.20—
Profit and Loss, Dr. to William Davidson.
Due David Henderson for repairs on the ship Elizabeth—
Ship Elizabeth, Dr. to David Henderson.

In some cases things are delivered by one person to another on the merchant's account. Thus, Thomas Anderson has paid the Royal Bank on my account L.40. Here the effect is the same as if there had been a double transaction,—as if Thomas Anderson had paid the merchant L.40, and the latter paid it to the Royal Bank, for which there would evidently have been the following entries:

Cash Dr. to Thomas Anderson.
Royal Bank Dr. to Cash.

But instead of making four entries in the leger, it is sufficient to enter the quantity in the accounts of the Royal Bank and of Thomas Anderson, omitting entirely the two entries on the opposite side of the cash account, which can have no effect whatever upon the balance. In that case the entry will run thus:

Royal Bank Dr. to Thomas Anderson:

And the rule will be, that

The person to whom any thing is delivered on the merchant's account,	Dr.	To the person who delivers it.

Things on hand at opening the books, and debts due to or by the merchant, are all entered in the inventory in the waste-book, from which they are transferred to the journal, and from the latter they are entered in the leger, the former in real, the latter in personal accounts, and all of them in the stock-account. Things on hand are entered, as we have seen, on the Dr. of real accounts; they must therefore be entered on the Cr. of stock. In the same manner, debts due to or by the merchant, which are entered, the former on the Dr. the latter on the Cr. of personal accounts, must be entered in the stock-account, the former on the Cr. the latter on the Dr. Hence the following rules.

The things on hand. The persons indebted to the merchant,		Drs. to Stock.
Stock,		Dr. to the persons to whom the merchant is indebted.

The application of these rules is sufficiently exemplified in the beginning of journal A.

In closing the books in the manner already described, the most regular way is to enter the results of the balance account in the journal. Thus, in order to close the real and personal accounts, the entries will be, for the profit and loss sheet,

Waste-book.

Profit and Loss Dr. to Sundries for articles of loss.
Sundries Dr. to Profit and Loss for articles of gain.
And for the balance sheet,
Balance Account Dr. to Sundries for articles belonging to me.
Sundries Dr. to Balance Account for articles due by me
And in order to close the accounts of stock, and of profit and loss, the entries are,
Profit and Loss Dr. to Stock for nett gain.
Stock Dr. to Balance Account for nett stock.

These entries are exemplified in Journal A, and balance account.

The above rules comprehend all the transactions of ordinary business; as illustrating also the general principles on which all journal posts are formed, they afford the means of forming with ease the proper entries of any more complex transactions that may occur; and, along with what has been said in the preceding chapters and the following specimen of books, will be sufficient to make the reader fully acquainted both with the theory and practice of this useful art.

Journal.

Besides the waste-book and journal, a variety of *subsidiary* books are opened in every extensive business to facilitate the composition of the leger, such as the cash-book, the bill-book, the books of accounts and invoices, the letter-book, &c.; these books contain all the details of the business which it would be inconvenient to enter in the others. Their nature is sufficiently obvious from their titles; and as their forms are quite arbitrary, we need not describe them more particularly.

(1.) WASTE-BOOK A.

Edinburgh, January 1. 1800.

				L.	s.	d.
INVENTORY of ready money goods and debts taken by me, A. B. this day.						
Ready money - -	L. 85	0	0			
100 bolls of oatmeal, at 20s.	100	0	0			
46 reams of paper, at 10s.	23	0	0

Boors.

BOORS, a general denomination of the Russian peasantry, who are under various degrees of bondage, according to the rank which they hold or the class to which they belong. The boors are divided into two great classes, the first includes the free peasants, who seem to hold a middle place between the free citizens or burghers, and the vassal boors, of which the second class is composed. The free peasants cannot be alienated or sold, they possess property, and, on paying the taxes and performing certain services, are permitted to enjoy the fruits of their labour; they are allowed to educate their children, and are exempted from all authority which is subordinate to that of the sovereign and laws of the state. The class of free peasants comprehends foreign colonists who have settled in Russia as husbandmen; those who are called one-house owners, who possess houses and lands as free property, for which they neither perform any feudal service, nor contribute any portion of their produce, but are bound to furnish recruits, and are prohibited from purchasing in villages, or having vassals as property; the various tribes of Cossacks, Baschkirs, Kalmucks, and the inhabitants of the Steppes in the southern regions of the empire; disbanded soldiers who have fixed their residence in the country; and vassals who have purchased their freedom from their superiors, or obtained it as a reward for their former services.

The vassal peasantry of Russia has been divided into three classes, private boors, boors of the mines, and crown-boors. Those who are included under the first class, belong to individual noblemen, on whose peculiar temper and dispositions their comfort and happiness depend; these private boors are bound to pay a certain sum annually to their masters, and to perform a certain quantity of labour, amounting sometimes to three days in the week; but the quantity of toil and of pecuniary tax being under no particular regulation, depends on the will of the lord. Women, as well as children above ten years of age, are compelled to contribute their share of these oppressive exactions. The boors of the mines are attached to particular establishments, and can neither be sold nor exchanged, but may be transferred to different masters along with the works. The crown-boors enjoy comparatively a much greater degree of freedom and comfort than those belonging to private individuals. The rent or tax exacted by government is generally more moderate; they are permitted to enjoy in security the benefits which arise from their improved condition; and, when they have acquired the means, they are allowed to purchase from noblemen villages and lands, with vassals attached to them. Those who are included in the class of crown-boors are distinguished by different appellations; some are called empire-boors, who seem to be in the rank of citizens, and belong to no particular institution or corporation, but are members of the empire; imperial-boors, who belong to the sovereign or to the court; monastery-boors, who were formerly annexed to the monasteries; and post-boors, who, on condition of keeping post-horses, are exempted from the usual tribute, as well as from other taxes.

Booshuanas.

BOOSHUANAS, a tribe of Caffres in southern Africa, who have arrived at a considerable degree of civilization. The first knowledge of this country and people was obtained in the year 1801, in consequence of an expedition which was sent from the

Cape of Good Hope to explore the interior of that part of Africa. The more recent visit of Mr Campbell, a missionary traveller, has added to the information collected concerning this region, which is represented as populous and fertile. Agriculture is successfully prosecuted, and abundant crops of grain and pulse are raised in inclosed fields. The natives of this country are remarkable for the simplicity of their manners, and are chiefly occupied in attending their cattle and hunting; but the women are very generally employed in the labours of the field.

The first visitors of this part of Africa were not a little surprised by the discovery of a large town, with a population of 10,000 or 15,000 inhabitants, besides many other towns and villages of considerable magnitude. Leetakoo, the chief town, is traversed by a considerable stream; the streets are not without regularity; and the houses, covered with reeds or straw, are of a circular form, and, as they are low, the town occupies a very large space. The inhabitants preserve their grain in jars of baked clay, each of which contains about 100 gallons, is elevated a little above the ground, and is furnished with a round straw roof. The country inhabited by the Booshuanas is included between the 20° and 28° of south latitude, and the town of Leetakoo stands in 26° 30′ of south latitude.

BOOTAN, a mountainous region of northern Hindostan, which is chiefly included between the 27° and 28° of N. lat. is about 200 miles in length, and about 60 or 70 miles in breadth, is separated on the north from Tibet by the Himalaya mountains, and has the province of Bengal for its boundary on the south; and while the unexplored regions north of Assam lie on the east, a district subject to the Nepaulese forms the limit on the west. The remarkable inequalities in the surface of this province produce striking diversities of climate. Of two places within sight of each other, the inhabitants of one, chilled by perpetual snows, experience all the rigours of winter, while those of another are exposed to the burning rays of an almost vertical sun. The mountains of Bootan form part of the great chain which appears in geographical descriptions under the name of Imaus, and which is of frequent occurrence in the mythological histories of the brahmins by the name *Himalaya*, *Himmaleh*, or snowy mountains. On the Bengal frontier, at the foot of this chain, a plain of about twenty-five miles in breadth presents an almost impenetrable mass of the most luxuriant vegetation; the trees are of immense size, and the thick forests, rarely disturbed by mankind, abound with elephants. The less elevated mountains are covered with perpetual verdure; and populous towns and villages are seen rising in the midst of orchards, rich plantations, and fertile fields.

Of mineral substances lime-stone, is chiefly noticed on account of its abundance.

Strawberries, raspberries, and blackberries, grow wild; the apple, the pear, the peach, the apricot, as well as oranges, pomegranates, and walnuts, are cultivated in perfection; and the ash, birch, maple, yew, and pine, and other useful trees, are abundant in the forests. The number of wild animals is small, but a large and handsome kind of monkey, which is held in great veneration by the inhabitants, is abundant; and the horse of Bootan is strong and active.

The robust and active mountaineers of Bootan form a remarkable contrast with their neighbours, the feeble-bodied and meek-spirited natives of Bengal. They are fairer in complexion than the Bengalese, have small eyes, broad faces, and high cheekbones, and are greatly subject to glandular swellings in the throat. In matters of religion the sect of Buddha prevails, and the priests form a distinct class; but the distinction of casts, which is so rigidly observed in Hindostan, is unknown. The supreme head of the province is the Deb Rajah, who resides at Tassudon, the capital, and has under him inferior governors and magistrates.

Woollen cloth for raiment, animal food, spirits, and tea, the latter of which is not less common as a refreshment in Bootan than in China, are in use among the inhabitants. The trade of the province is probably not very extensive, but a caravan annually visits the district of Rungpoor in Bengal, and brings with it oranges, walnuts, and the coarse woollen manufactures of the country, with the horses that carry them, for sale; and among other commodities which were sent by the Rajah of Bootan to the presidency of Bengal, some of the precious metals, as gold and silver, musk, woollen cloths of Tibet, and silks of China, are enumerated, from which it appears that some intercourse exists between this province and those countries.

BOOTON, an island in the Indian ocean near the south-eastern extremity of Celebes, and in 5° of S. lat. is about 85 miles long and 20 miles broad; the surface is high and woody, but in many places is well cultivated, and produces rice, maize, yams, and various tropical fruits; fowls, goats, buffaloes, and fish, are sold to ships which touch at the island; and the inhabitants, who speak the Malay language, and profess the religion of Mahomet, are of a short stature and tawny complexion. The Dutch had formerly a settlement in the bay of Booton, and for the payment of an annual tribute to the chief of the island they were permitted to inspect the woods and destroy the clove trees, that, agreeable to their jealous policy, none but themselves should enjoy the benefit of the trade in that spice. A gulph from the east side of this island has received the name of Mistake-bay, from the extreme difficulty of a ship that has once entered it being extricated, in consequence of the strong currents which constantly flow into it. A Dutch governor, on his passage to Banda, was detained a whole year in this bay.

BOPAL, a town in the province of Malwah, and capital of a territory of the same name in Hindostan. This small state is tributary to the Mahrattas. The town is of considerable extent, surrounded with a stone wall, and secured with a fort built on a solid rock. Under the walls of the fort, a tank, or pond of water, six miles in length, is formed by an embankment at the confluence of five streams which issue from the neighbouring hills. The town and territory of Bopal are occupied by a colony of Patans, to whom they were assigned by Aurengzebe.

BORACIC ACID, a peculiar acid, which forms one of the constituent parts of the native salt borax, and the base of which, *borone*, according to recent discoveries, is analogous to carbone in some of its properties. See Chemistry.

BORACITE, a mineral substance, composed chiefly of magnesia, lime, and boracic acid. See Mineralogy.

BORAGO, Borage, a genus of plants belonging to the Pentandria class.

BORAX, a native salt, which is collected in the East Indies, and is employed in medicine and the arts. See Chemistry and Mineralogy.

BORBONIA, a genus of plants belonging to the Diadelphia class.

BORDA, John Charles, an eminent French mathematician and natural philosopher, was born at Dax, in the department of Landes, in 1733. Having completed his elementary studies, he was placed under the superintendence of the Jesuits, who well knew how to appretiate his talents, and were anxious to number him among their members; but the early and strong bias which he discovered for mathematical researches opposed all solicitation to seduce him to other studies. The father, who had a large family, was desirous that his son should be placed in some situation the emoluments of which might be equal to his support; and with this view the young mathematician reluctantly spent several years in an office connected with the municipal authorities of the country. Relieved from this drudgery, by the advice of a friend, Borda had soon after the good fortune of becoming acquainted with the celebrated D'Alembert, and at his recommendation he entered the French cavalry, and at the same time continued to prosecute his mathematical studies. In his twenty-third year he presented a memoir on the motion of projectiles to the academy of Sciences; in the succeeding year was present at the battle of Hastembeck, where he acted as aid-de-camp; and soon after his return was nominated inspector of the dockyards, an appointment peculiarly suited to his genius and studies. The researches which occupied his attention while he held this office relate to an examination of the theories of the resistance of fluids, the motion of fluids, water-wheels, the construction of water-pumps, and the theory of projectiles.

The application of Borda's mathematical knowledge was now to take a wider range; and, with this view, contrary to ordinary usage, he was appointed an officer in the French navy; and the first service in which he was engaged was, in conjunction with an associate, to try the chronometers, or time-pieces, which were proposed for finding the longitude at sea. This voyage was performed in 1771 and 1772; he was afterwards employed on a survey of the Canary islands, for the purpose of ascertaining their precise position; and he attained the rank of major-general to the armament under the count D'Estaing, who had so large a share in the naval operations of the war which terminated in the separation of America from the parent state. Having obtained afterwards a higher rank in the navy, he was entrusted with the command of several frigates under the orders of the famous count de Grasse, by whom he was appointed to a cruizing station; but his little fleet, after a brave resistance, was compelled to surrender to a British squadron. But the mortification for the loss he had sustained, and the state of his health, which had suffered greatly by long and arduous service, led to the resolution of relinquishing the active duties of the profession, and spending his days in study and retirement. M. Borda seems to have taken an active part in the French Revolution, for he appeared as a candidate for the office of a director of the republic; he had some concern in the improvement of weights and measures; he entered keenly into the grand national schemes for trigonometrical surveys; and he instituted many ingenious experiments on the changes which metallic rods of different kinds sustain by difference of temperature. He died in 1799, when he had reached the 64th year of his age.

BORELLI, John Alphonso, an eminent Italian physician, was a native of Naples, and was born in 1608. Having acquired considerable reputation by his progress in geometrical science during the period of his education, which was completed at Rome, he was appointed to teach mathematics at Messina in Sicily; and during his residence in that island, a malignant fever, which carried off great numbers of the inhabitants, prevailed, and of this fever he afterwards published a detailed account. Borelli held for some time the professorship of philosophy and mathematics at Pisa. He spent the latter years of his life in retirement at Rome, under the patronage, it is said, of queen Christina of Sweden, who then resided in that city; and having reached the 72d year of his age, he died in 1679.

Borelli was highly respected by his cotemporaries; he corresponded on scientific subjects with some of the principal philosophers of the age; and he was the author of numerous treatises on mathematics, natural philosophy, and medicine. But in his most interesting work, *De Motu Animalium*, a posthumous publication, he applies the laws of statics to the motions of living beings. In this elaborate investigation, his object is to estimate, not only the individual, but the collective power of the fibres of a muscle, and to point out the variations in their effects according to the mode of insertion and action.

BORGIA, Cæsar, one of the most conspicuous characters of the concluding part of the fifteenth and the commencement of the sixteenth century, but distinguished by his vices, especially his ambition and cruelty, was the son of cardinal Roderigo, who was raised to the papal throne in 1492, and assumed the name of Alexander VI. The elevation of his father enlarged his ambitious views, and the hope of realizing those schemes of greatness which were suited to his aspiring temper, induced him to appear at the court of the Vatican, for the purpose of securing some share of the power and influence of the head of the church. But although his reception was cold and formal, and his disappointment extreme, yet he was soon after preferred to the archbishopric of Valenza, and in the succeeding year elevated to the dignity of cardinal. The influence attached to the high station which Borgia now filled, rendered him a fit instrument in the hands of a father equally ambitious and depraved, in those political struggles in which he was concerned. Among the first atrocities which marked the flagitious career of Cæsar Borgia, was the death of his brother, who, at his instigation, fell by the hands of assassins, in consequence, it is said, of the marked preference which the father discovered towards his eldest son, or of jealousy in finding him his rival in the affections of a lady to whom he was attached. The father's grief and resentment at this barbarous deed were appeased by a hint from the mother of Borgia, that the same fate, and from the same unseen hand, awaited himself if he should persevere in his enquiries concerning the perpetrators of the murder.

Aspiring to higher distinctions and greater power, Borgia was employed in a mission to the French court in the character of ambassador, was raised to the rank of nobility by Louis XII. with a large pension, and soon after married the daughter of the king of Navarre. He now appeared in a military capacity, and took the command of a party of troops for the purpose of reducing Romagna into subjection to the Holy See. The success of his arms alarmed the Italian states, and produced a confederacy against him; but the cup of poison and the secret blow of the assassin were not less effectual in defeating its object, and in accomplishing the wicked projects of the father and son, than the vigour of open warfare.

The vicious career of this accomplished villain now approached to its termination. To obtain possession of the wealth and property of some bishops, the usual means were resorted to; poison was prepared for the purpose, but the deadly mixture intended for others, by the mistake or design of those who were employed to administer it, was swallowed by the pope and his son. The pope died; but the strength of the son's constitution resisted its effects. Providence seemed to permit him to live, that he might experience adversity and poverty as a punishment for his crimes. Banished from the papal dominions, he narrowly escaped with his life, and found no asylum in any other territory except in the walls of a prison. After two years close confinement in Spain, he escaped from a window by means of a rope; and thus, stripped of all his honours and possessions, degraded and destitute, he fled to his brother-in-law the king of Navarre, who was then at war with some of his rebellious subjects. Borgia entered the service as a volunteer, and was slain in a skirmish in the year 1507; thus leaving to mankind a memorable example of the vicissitudes of fortune, and of the effects of lawless ambition, profligacy, and villainy.

BORING-MACHINE, an apparatus which is employed for the purpose of boring pumps or cylinders, and of rendering their diameters equable and straight. Great precision in the construction, and great accuracy in the operation of such machines, are necessary. The following is a description of an improved boring-machine for the purpose.

A, *Fig* 1. *Plate* 27. is a pinion driven by the steam-engine or other power, and communicating motion to the wheel C. B lever for engaging and disengaging the motion. D D D, axis of the wheels. E, pinion on the axis communicating motion to the wheel F. G G G, coupling box with pinching screws, for driving boring-bar. I I I, plummer-block for the axis D. J J, strongiron plate for fixing and holding down the shafts DG. K K K K, strong bolts for holding down plummer blocks I I. L L, strong mason-work. M M, level of floor upon which the rail-road is placed. N N N N, end view of rail-roads upon which the boring carriage to be described moves. O O O, end view of racks for advancing the carriage forward to the cutter-block. P P P, end view of walls or foundations to which rail-roads are fixed. Q Q Q Q, strong holding down bolts for rail-roads.

Fig. 2. Perspective view of boring carriage for small work. A, pump to be bored. C, Boring-bar. D, carriage advanced forward by the lever E and weight F, by means of the pinion G, working into the rack H. I I, rail-road. J J, carriage wheels moving on rail-road.

Fig. 3. Section of boring-bar for larger cylinders. A, coupling box. B, coupling shaft. C C C, standards for carrying boring-bar and framing for wheel work. D, hollow boring-bar turned on the outside to a complete cylinder, upon which the accuracy of the work entirely depends. E, cutter-wheel moved along the bar D by the screw F in the inside of the hollow bar. G, pinion on boring-bar working into the wheel H, giving motion to the shaft I, and pinion K, working into the wheel L, which gives motion to the screw F, for advancing forward the cutter-wheel E.

Fig. 4. End view of standard for supporting the bar.

Fig. 5. Cutter-block for hollow bar, Fig. 3; 1, sliding box which is accurately fitted on the hollow bar, and upon which the different sizes of cutter-blocks are keyed by the keys 2 2 2.

Fig. 6. Cutter-block for smaller work. 1 1 1, steel cutters. 2 2 2, wooden wedges for keeping the cutter-block steady.

The motion of the different shafts is best regulated by the alteration of the first moving power, A, Fig. 1. The wheel C with its shaft, Fig. 1. should move from two to three revolutions in the minute for small work, and the wheel F from a half-revolution to one revolution in a minute, for cylinders or larger work. The ingenious mechanic will readily perceive, that with a sufficient moving power the apparatus may be extended, and any number of borers may be employed at the same time. In some works the boring of six or more pieces of work is going on at once.

For the description and information relative to the above apparatus, we are indebted to Mr Gutzmer, the proprietor of the foundery, Leith Walk, Edinburgh, whose ingenuity and accuracy, in the construction aud fitting up of machinery, are deservedly acknowledged by all who have had the benefit of his talents.

BORMIO, a district in Switzerland, about 15 miles in length and the same in breadth, and forming part of the country inhabited by the Grisons, is surrounded almost on all sides by the lofty Rhetian Alps. It is in general extremely fertile; on the hills, besides extensive woods that adorn their majestic brows, the inhabitants rear numerous herds of cattle; and the valleys, if well cultivated, might produce abundant crops of grain. But agriculture is not the chief object of the inhabitants, as appears from the number

BORING-MACHINERY.

Born.

of exported cattle, and the quantity of imported corn; for although Bormio is nearly encompassed with high and rugged mountains, they trade with every country that surrounds their territory,—exchanging the produce of their hills, mines, and dairies, for the wine of the Valteline, the cloth of Germany, and the corn of Tyrol.

The climate of this district is keen, but pure and salubrious. The population is about 14,000; and the Grisons when called upon to defend their territory, or to maintain their rights and privileges, can bring into the field a formidable force.

BORMIO, the capital and principal town of the district of the same name in Switzerland, stands in a delightful situation between two rivers. The general aspect is extremely mean; and even the residences of those of superior rank, as well as the public buildings, display little taste either in beauty of architecture or internal convenience; yet some of them might be regarded as ornaments of the place, were they not disfigured by miserable huts in their vicinity. At a short distance from the town are the famous warm baths of St Martin's, greatly esteemed for their virtues in the cure of various diseases.

BORN, Inigo, better known by the name of Baron Born, an eminent German mineralogist, descended from a noble family in Transylvania, was born in 1742, was educated in the Jesuits college at Vienna, and after a tour through various parts of Germany, Holland, and France, he returned to Prague, commenced the study of natural history and mining, and in 1770 was admitted into the department of the mines and mint established in that city. In the same year he travelled through Transylvania and Hungary, and the detail of the information collected on this journey, chiefly relative to mineralogy and geology, was published in a series of letters addressed to the celebrated naturalist Ferber; a translation of this work from the German afterwards appeared in English. While on this journey he had nearly lost his life by descending into a mine at Felso-Banya, in which some wood had been burnt, the smoke of which was not dissipated. In the succeeding year he was appointed counsellor of the royal mines in Bohemia, and continued through life to devote a large portion of his time to mining operations, and to the improvement of the processes which are employed in separating the precious metals from their ores, and particularly of the process of amalgamation, on which he afterwards composed a treatise, which was also published in an English translation. Baron Born had a considerable share in the secret associations, under the name of free masons and illuminati, which prevailed in Germany during his time; and as he possessed talents for humour, he was not scrupulous in indulging his satirical powers against some of the institutions and monastic orders of the Romish church. Having suffered much through life from the accident which befel him in the mine of Felso-Banya, he died in the year 1791, leaving a wife and two daughters not only to lament his loss, but to feel the effects of the embarrassed state of his affairs, arising chiefly, it is supposed, from the expensive nature of the experiments in which he was concerned.

Baron Born was the author of several other works, particularly a catalogue of his own mineral collection, which he afterwards disposed of to the honourable Mr Greville, and which forms a part of that gentleman's splendid collection purchased by the public, and now deposited in the British Museum; the catalogue of Miss Raab's collection of minerals; and a superb work on conchology, descriptive of the shells in the imperial cabinet. To his praise it is recorded, that the learned stranger who visited Vienna never failed to experience his hospitality; and unprotected genius always found in him a warm friend and a liberal patron.

Borneo.

BORNEO, one of the Sunda islands, extends from the 8th degree of north latitude to the 4th degree of south latitude, and from the 109th to the 119th degree of east longitude; is in breadth about 800 miles, and in length about 700 miles, and, before the discovery of New Holland, was supposed to be the largest island in the world. Though situated beneath the equator, and exposed to the rays of a vertical sun, it enjoys a mild and salubrious climate, free from oppressive heat, and purified by gentle breezes and refreshing showers. It is extremely fertile in animal, mineral, and vegetable productions. Of the former, elephants, bears, tigers, buffaloes, orang-outangs, and a peculiar species of black and white ape, are abundant; and on the sea coast is found a sort of snail, which forms a valuable commodity in the trade to China. Among the mineral productions may be mentioned tin, iron, copper, gold, and diamonds, the last of which are likewise found in several rivers, are supposed to be of a finer water than those of Hindostan, and constitute a lucrative branch of commerce. The vegetable productions, as the various sorts of delicious fruits, vast quantities of pepper, and other spiceries, and, in the northern parts, the extensive forests of excellent kinds of timber for various purposes, give ample proof of a rich soil and genial climate.

The inland parts are mountainous, and inhabited by the Idaans and Biadjoos, a race of savages who boast in the number of victims that fall a sacrifice to their barbarity, and whose skulls they expose in public as trophies of their valour. In their marriage and funeral ceremonies the same inhuman custom is observed. In the former it is necessary that the suitor, before he can obtain the consent of the parents of his intended bride, produce the head of an enemy as a token of his courage; and in the rites of the latter a similar cruelty is practised, by the friends of the deceased putting to death a slave in order to attend his master in another state. These barbarians, though they have no sovereign of their own, in some degree show respect to the sultan of Banjar-massin, by giving annually a little gold-dust; yet they acknowledge the authority of a chieftain, whose power is confined within narrow limits. No regular code of laws or form of government exists; but when any trespass is committed to the prejudice of an individual, and no sufficient evidence is produced to convict the accused, a method is adopted, similar to the trial by ordeal, to ascertain his innocence or guilt.

The coasts of Borneo are inhabited by the Moors, a people more civilized in their manners, and contains seven provinces or kingdoms, the largest of which, Banjar-massin, is celebrated on account of various attempts by Europeans to form a junction with the natives for commercial purposes. The first was made by the Portuguese in 1526; in this attempt they failed; but about the close of the 17th century they were allowed to establish a factory, and by the treachery of the Moors the whole settlers were murdered, and their vessels and property seized. The Spaniards also visited the island, and were equally unsuccessful. The Dutch likewise endeavoured to plant a colony, but being at first disappointed, they appeared again on the coast of Borneo, and obtained permission to erect a factory at Banjar-massin, under certain regulations. The English, in their turn, attempted several times to form a settlement. Their first landing, in 1694, proved entirely fruitless; but when they arrived a second time, the natives appeared more friendly to their wishes, and, by the assistance of a number of Indians, a colony was begun, which had a promising appearance, yet, falling short of several necessaries of life, they were obliged to abandon it. The third time they landed on the island, to regain possession of their colony, the Moors attacked them, but were driven back; and the brave commandant, Captain Barr, dying in 1706, two years after the forming of the establishment, and the command having devolved on Cunningham, a weak and cowardly person, the colony was assaulted and given up, the governor with his whole garrison embarked for England without offering the least resistance, and the enemy plundered their stores, and destroyed the extensive works. And, in 1766, a settlement was formed in another quarter, which, after existing a few years, was entirely destroyed by the natives; yet in Borneo, the capital of the kingdom of that name, the English have still a factory, and retain possession of the northern coast of the island.

Before this portion of the globe was known to Europeans, the Chinese were in possession of the principal trade of Borneo, and a large share still remains in their hands. For various kinds of wood, tortoise-shell, spiceries, gums, camphor, and swallows nests, they exchange silks, chintz, calicoes, and the different manufactures of China and Japan.

BORNEO, a sea-port town of the island of Borneo, and capital of a kingdom of the same name, which occupies a marshy situation on the banks of the river Borneo, on the north-west quarter of the island; the houses are raised on piles of wood; the communication is by boats on the river, or canals; and a considerable trade is carried on between the natives and foreigners who frequent the harbour.

BORNHOLM, an island in the Baltic, subject to Denmark, is about six miles in length, and three miles in breadth, and is sixteen miles distant from Zealand. All kinds of grain are raised, and excellent pastures afford nourishment to sheep and cattle. The number of inhabitants is estimated at 30,000, and they are distributed into six small towns and numerous farm-houses in every part of the island. The fishing of herring, cod, and salmon gives employment to a large proportion of the population, and in the curing and smoking of salmon they are particularly successful.

BORNOU, an extensive region of Africa, which is included between the 22° and 27° of N. lat. and is bounded on the S. E. by Fezzan, and on the W. by Nubia. The heat is often excessive, and deluges of rain, and tempests of thunder and lightning, which are often highly destructive, are frequent. As in other districts of Africa, fertile spots and barren wastes cover the surface of Bornou. Indian corn is much cultivated; cotton, hemp, and indigo thrive well, and the rich fruits of tropical climates are abundant. Sheep, goats, cattle, buffaloes, horses, and camels are reared, and the lion, the leopard, the wolf, and the antelope, are enumerated among the wild animals. The houses are constructed in the same manner as in other regions of Africa, and the towns are composed of straggling houses.

The inhabitants of Bornou are of a black complexion, but have features somewhat different from those of the negro race. Some of them profess the religion of Mahomet, but the larger portion is addicted to pagan superstition. The government is a kind of monarchy, but the sovereign is elected from some one of the royal family, according to the choice of three persons of respectable character; this arbitrary mode of election is no doubt influenced by force and cunning, and is the fertile source, among a rude and turbulent people, of frequent revolutions and barbarous murders. Coarse linen and some cotton stuffs, a kind of carpets, and a coarse cloth of goats and camels hair mixed with wool, are manufactured in the country; and gold-dust, ostrich feathers, salt, some perfumes, horses, and slaves, are the chief commodities for their commercial intercourse with Tripoli.

Bornou, the capital of the empire, is a town of considerable extent, and is 600 miles S. E. from Mourzouk.

BOROUGH, or BURGH, from the Saxon borgh, usually denotes a town or corporation which has not the rank of a city, but is particularly applied to towns which possess the privilege of sending representatives to parliament. Borough is supposed by some to have originally meant a tything, or community of ten families, who were conjoined and bound together as pledges for the conduct of each other. The term borough afterwards was employed to denote a town which was fortified by means of a wall or some kind of enclosure, and, in latter times, country towns of any note, whether walled or not, had the same appellation. Cities were denominated boroughs by the ancient Saxons, but the episcopal sees being removed from villages and small towns, the name of city was limited to episcopal towns, and the denomination of borough was retained by all others. The boroughs of England are distinguished into those which enjoy their rights by statute or charter, and by prescription or custom, and some of them send one and others two representatives to parliament.

The boroughs of Scotland are either royal boroughs or boroughs of regality. The first are constituted by charter of the sovereign, and have the power of electing annually their own magistrates, whose authority extends to the regulation of all matters of police connected with the corporation, and, within a limited extent, to civil and criminal matters. The whole of the boroughs of Scotland return fifteen members to the British parliament; so that several boroughs, generally five, unite in the election of a member.

The convention of royal boroughs, which was constituted by James III. in 1487, and consists of deputies or commissioners from each of the royal boroughs, first met at Inverkeithing, and is now held annually at Edinburgh, for the purpose of considering and regulating all matters relative to trade and the general interests of the boroughs.

The right of electing magistrates in boroughs of barony and regality, is sometimes committed to the inhabitants themselves, and sometimes retained by the baron or superior; the powers of the magistrates of such boroughs are more limited than those of royal boroughs, and extend chiefly to the cognizance of debts, and questions of possession between the inhabitants.

BOROUGH ENGLISH is a peculiar descent of lands or tenements in some ancient boroughs and copyhold manors, by which the youngest son succeeds to the possession on the death of the father, the reason of which, as it is assigned by some, is the tender age of the youngest son, by which he is less able to provide for himself; but by others this custom is traced to the pastoral state of society, such as exists among the Tartars at the present day, among whom the elder sons are allowed a certain portion of cattle, and seek a new habitation, while the youngest son remains longest with the father, and becomes the heir of his possessions. This custom also prevails among some northern nations, and is alluded to by Cæsar and Tacitus.

BOROUGH-HEAD, or HEAD-BOROUGH, or Tything-man, was the chief man of a tything or hundred, and was chosen annually, according to the institutions of Alfred, to preside over its affairs; but the appellation Head-borough is now applied to a kind of head constable.

BORROWSTOWNNESS, sometimes called BO'NESS, a town of Linlithgowshire in Scotland, stands on a point of land on the south side of the frith of Forth, and is 18 miles N.W. from Edinburgh; the streets in general have no great regularity, but contain some good houses, besides extensive warehouses for grain and merchandise. It became a place of some importance about the beginning of the 18th century. The population stated at 2613 in 1794, had only increased to 2919 in 1811; but the trade, both foreign and coastwise, which was at one time considerable, had greatly declined. The manufacture of salt, which has been long extensively conducted, of sal ammoniac, soap, and of earthen and stone-ware, derive great facilities from the abundance of coal in the neighbourhood. Some ship-building is also carried on; and many of the women in the town and vicinity are occupied in tambouring, and in the spinning of silk for stockings.

BOSCOVICH, ROGER JOSEPH, an eminent mathematician, and the founder of a theory of natural philosophy, was born at Ragusa in Dalmatia on the 11th May 1711. His earlier years were spent at the schools of the Jesuits in his native place, and gave promise of the eminence and reputation to which he afterwards attained. He was removed to Rome in 1725, according to the policy of the Jesuits which enjoined the supreme care and education of those pupils who exhibited the greatest talents and most effective improvement. Here he took the habit of the noviciate, cultivated theology and general science, perfected himself in classical studies, and from the station of private teacher was at last promoted to the professorship of mathematics; for which department of knowledge, notwithstanding the variety of objects presented to his ambitious and enterprising mind, he continued to display the strongest genius and predilection. In the discharge of the duties of his office, he composed several elementary treatises on different branches of the science, some of which have very uncommon merit. He had the rare and valuable art of combining strictness of reasoning on profound subjects with the rich and varied product of a lively fancy, and those embellishments of taste and manner which never fail to captivate attention. A considerable talent for the composition of poetry furnished him with topics and illustrations, and a facility in reciting verses yielded gracefulness and the most imposing effect to his stated labours and ordinary conversation. These and other excellencies soon raised him to the highest distinction and secured general applause, whilst the extent of his learning, the depth and solidity of his judgment, the acuteness and inventive power of his genius, added to the integrity and amiableness of his character, formed the substantial means of supporting and enhancing any reputation which he acquired.

The fame of Boscovich, accordingly, in a short time, travelled much beyond the circle of his acquaintance, or even his extensive official responsibility. Foreign societies appear to have vied in the abundance of honours which they conferred on him; and his advice and assistance were thought worthy of being solicitously applied for in order to determine the disputes of various princes and states. An engagement of this kind, in behalf of his native country, brought him to London, where he was favourably received, and where he had the satisfaction of obtaining a title, certainly not less flattering than any that had hitherto graced his name, that of a Fellow of the Royal Society. During his residence in this city, he published his work *De Solis ac Lunæ Defectibus*, and dedicated it to the body of which he was thus chosen a member. It is one of the few examples of didactic poems, in which the principles of science are happily blended with the offspring of creative imagination, and the beauties of language. Boscovich accomplished the object of his mission, and prepared to return home, but not before receiving another proof of the respect in which he was held. This was an invitation by the Royal Society to accompany some of its members destined for America, to observe the approaching transit of Venus, which, for various reasons, he found it necessary to decline.

Accompanying a friend whom he met at Venice, he visited the plain of Troy, and afterwards resided a short time at Constantinople, and having traversed Bulgaria, Moldavia, and part of Poland, projected a journey to Petersburg, but abandoned his intention on hearing of the death of the Emperor Peter. Some time after his return to Rome, Boscovich was appointed to the professorship of mathematics in the university of Pavia, which was soon relinquished for the chair of astronomy and optics at Milan, under the patronage of the Empress, and with the superintendence of the observatory at Brera. The envy or contemptible jealousy of some of his contemporaries and colleagues, had ere now invaded the philosophical retirement and indulgence which he had promised himself in the evening of his days; and he had already experienced an attack on his health which threatened his dissolution, and from which it is doubtful if he ever thoroughly recovered.

The suppression of the order of the Jesuits, which took place in 1773, augmented his distress, and prevented the plan he had formed of retiring for the remainder of his days to his native city, in hopes of enjoying that tranquillity and affection which seemed so necessary to his existence. He finally determined, in his embarrassments of mind, body, and estate, to retire to Paris, where he had, when once on a visit, been so hospitably entertained, and where it was supposed the respectability of his character, and the amount of his services to science, could not fail to procure an adequate establishment and comfort. The munificence of the French monarch, through the interest of the chamberlain La Bord, one of his friends, so far realized these hopes, as to appoint him director of optics for the marine, with a salary of more than L.300 sterling,—a sum fully commensurate to his moderate habits. But this liberality could hardly soften down some strong prejudices which he manifested against the manners and principles of his new associates, and the French in general, and far less could obviate a very visible inclination on the part of many to detract from his merits, or to suggest that they had been too amply rewarded.

The keen feelings of the Ragusan, and a conscientious regard to religion, bitterly contended with his sense of duty and a conviction of necessity, for about ten years, when he solicited and obtained leave of absence to visit his friends in Italy. At Bassano, in the state of Venice, which was the first place where he now resided for any considerable period, he published a collection of some of his works, in five vols. 4to, and in the Latin, Italian, and French languages. This abounds in curious, profound, and valuable dissertations on mathematical and philosophical subjects. He afterwards travelled to Rome, in order to see some of his early acquaintances, and thence to Milan, where the resumption of his studies, and the felicity of a respected and respecting society, shed a ray of pleasure on the shortening period for which his leave of absence had been granted. But in proportion to its intensity was his apprehension of misery as the effect of fulfilling his obligations to royal favour. His mind, long harrassed by dread of encountering a renewal, perhaps an aggravation, of the jealousies and discordancies which had formerly assailed him, urged on by solicitude at the same time not to appear wanting in gratitude, and, in all probability impaired in the natural course of bodily infirmity and advancing age, at last sunk in the conflict. A state of derangement ensued, not, however, without some lucid moments, which at one time gave room to anticipate comparative restoration. A relapse followed, and an imposthume bursting in his breast, he was released from suffering on the 13th of February 1787, in the 76th year of his age. "Such was the exit," says one of his biographers, Fabroni, "of this sublime genius, whom Rome honoured as her master, whom all Italy regarded as her ornament, and to whom Greece would have erected a statue, had she, for want of space, been obliged even to throw down some of her heroes."

Boscovich was tall and robust; his complexion was sallow; his temper was somewhat irritable; and a degree of vanity was conspicuous in his usual deportment, and still more in his frequent allusions to his own works; but it was compensated by liveliness of wit, elegance and fluency of conversation, and the more estimable qualities of cordial friendship and benevolence of disposition.

Of the works of Boscovich, which are too numerous to be specified, Dr Hutton's classification may suffice. 1. Elements of Mathematics, with a Treatise on Conic Sections. 2. His many Dissertations published during his professorship in the Roman college. 3. His account of the Survey of the Pope's Estate. 4. His Poem on Solar and Lunar Eclipses, already mentioned. 5. The five volumes published at Bassano. 6. His Hydrodynamical works. 7. A Theory of Natural Philosophy. This last work is said to have been composed in thirty days. It was first printed at Vienna in 1758; and a second edition, *ab auctore perpolita et aucta*, appeared at Venice in 1763, a presentation copy of which to an illustrious character in our own country is now in the hands of the writer.

BOSJESMANS, or BOSHIESMEN, a tribe of Hottentots who occupy an extensive district at the Cape of Good Hope; they derive this name, which is equivalent to Bushmen, from having their abodes in woody and mountainous places. They are described as a rude and barbarous people, of small stature, and are said to be the ugliest of all the savage tribes; they have scarcely any covering to their bodies, and their precarious subsistence chiefly depends on plunder, or on locusts, and the spontaneous productions of the soil. The arms which they employ in their predatory excursions are bows and arrows, and lances, and it is said that they use poisoned weapons. These savages have often been extremely troublesome to the Dutch colonists, by whom they are treated with great barbarity, and hunted like wild beasts. According to the relation of Mr Barrow, one colonist boasted of having shot not fewer than 300 of that unfortunate tribe with his own hand. Those who are taken prisoners are doomed to slavery the rest of their lives.—*Barrow's Travels in Southern Africa.*

BOSNIA, a mountainous province of European Turkey, so called from the river of that name which passes through it and falls into the Save, is bounded on the N. by Sclavonia, on the east by Servia, on the S. by Servia and Albania, and on the W. by Dalmatia and Croatia, and is about 120 miles in length, and 72 in breadth. The soil is fertile, particularly near the rivers, producing good wheat; numerous herds of cattle are reared on its excellent pastures; and it is also enriched with silver mines. Bosnia exports to Sclavonia, raw skins, wool, and cotton, but not to any extent, and at other small ports the Bosnians exchange their cattle, where weekly fairs are held, under the cognizance of a customhouse-officer.

This province was anciently part of Pannonia, but became, in course of time, part of Hungary, was erected into a kingdom, and governed by its own kings till 1465, when the Turks became its masters. The inhabitants are Greek Christians, with some Mahometans, Jews, and Catholics. The capital of the province is Banjaluka.

BOSPHORUS, from two Greek words signifying the passage of oxen, is chiefly applied to the straits of Constantinople, or the Thracian Bosphorus, and to the straits of Caffa, or the Cimmerian or Scythian Bosphorus, which joins the sea of Azof with the Black sea. The narrowness of these straits, which permitted an ox easily to swim across, according to one opinion, gave origin to the name; but, according to another, it was derived from a market for cattle being held in its vicinity. The Thracian Bosphorus is about twenty miles in length, and two miles in breadth; the breadth of the Cimmerian Bosphorus is stated at twelve miles.

BOSSUET, James Benigne, an eminent French divine, and eloquent preacher, was born at Dijon in 1627, commenced his studies among the Jesuits, and completed his education at Paris. He was early destined to the clerical profession; and by the study of the sacred writings, the ancient fathers of the church, and the classical productions of Greece and Rome, he soon distinguished himself by varied acquirements and extensive learning. At the age of sixteen he displayed remarkable powers for eloquence, and became one of the first preachers in France. The reputation of his splendid talents reached the court, where he obtained the favour of Louis XIV. was promoted to a bishopric, and afterwards intrusted with the charge of the dauphin's education. For the use of his royal pupil his *Discourse on Universal History* was composed, one of the most valuable of his works, which is still read with advantage, and admired as a comprehensive sketch of the subject. When he entered on the duty of superintending the studies of the heir of the throne of France, Bossuet had resigned his bishopric; and when he had finished this task, his fidelity and diligence were rewarded by his promotion to the see of Meaux. In this dignified station he devoted himself with great assiduity to the service of religion, and was not less zealous in defence of the catholic faith. This led him into numerous and violent theological controversies, in which he displayed great acuteness and vigorous powers of argumentation. But in the midst of these disputes the harshness and severity with which he opposed the views and doctrines of the amiable and celebrated Fenelon, a member of the same church with himself, have been justly censured and generally regretted; and although the piety and zeal of the bishop of Meaux have been rarely called in question, or ascribed to any other motive than sincerity of conviction, yet his conduct in this case seems not altogether divested of invidious feeling.

Retiring from the splendour and bustle of a court, Bossuet devoted the last years of his life to the useful and unobtrusive duties of a Christian minister; and the same person who had acquired such distinguished reputation on the great theatre of the world, was equally assiduous in dispelling the darkness of ignorance by the light of truth, in pouring the balm of consolation into the wounded mind, and in providing for the temporal wants of the indigent and unfortunate among the meanest of his flock; In the midst of these humble and important services, he closed his mortal career in the year 1704. The sermons of the bishop of Meaux, which have been printed, are less to be regarded as finished compositions than rapid sketches; but they exhibit ample proofs of powerful genius; and his funeral orations, which are distinguished by elevated sentiments and tender effusions, are universally admitted as unrivalled productions.

BOSTON, a town of Lincolnshire, in England, stands on the banks of the river Witham, about five miles distant from the sea; the town is well built, and has been greatly improved of late years; a spacious market-place is adorned with a fine cross; and St Botolph's church, the building of which commenced in the beginning of the 14th century, is a magnificent structure, and the largest parochial church, without cross-aisles, in Europe. Its lofty tower, which rises to the height of 282 feet, serves as a landmark to mariners. The correspondence of the pillars, windows, and steps in this church and tower, to the months, weeks, and days of the year, is somewhat singular. The population, in 1811, exceeded 8000, and the inhabitants are employed both in foreign and coasting trade. The river is navigable for small vessels to the town.

BOSTON, the capital of Massachussets and of New England, in North America, occupies a peninsular situation at the bottom of Massachussets' bay. The town is disposed in a crescent form round the harbour, and the country rises gradually behind it, presenting, to those who approach it from sea, a singularly beautiful and picturesque scene. Boston is indebted for its origin to a colony from Charlestown in 1631; in 1727 it sustained great damage from an earthquake; and, since that time, as the houses are chiefly of wood, has repeatedly suffered from destructive fires. Many of the public buildings are magnificent structures, and two bridges over Charles' river are not less ornamental to the place than commodious for the inhabitants; the harbour is spacious and convenient, and capable of admitting 500 sail to ride at anchor; and the narrow entrance is defended by a fort, erected on an island, and well furnished with heavy artillery.

The population of Boston, which was estimated, in 1790, at 18,000, exceeded 20,000 in the year 1800. Sail-cloth, cordage, sugar-refining, hats, glass, tobacco, paper hangings, cards for wool and cotton, and playing cards, are the principal manufactures; the trade, foreign and coastwise, is considerable; and charitable institutions, as well as those for promoting the improvement of arts and literature, are numerous.

BOSWELL, James, the celebrated biographer of Dr Johnson, was the son of Alexander Boswell, the representative of an ancient family in Ayrshire, and a judge of the supreme civil and criminal courts of Scotland, who, on his elevation to the Bench, in compliance with the custom of the

Boswell. country, assumed the distinctive title of Lord Auchinleck, the name of his patrimonial estate. James, the subject of this notice, was born in Edinburgh, October 1740. His education, for which, from the beginning, he discovered a high degree of aptitude, commenced in his father's house, and was successfully prosecuted at the school of Mr Mundell in Edinburgh, and afterwards at the universities both of that city and of Glasgow. In the twentieth year of his age he visited London, and happening to form an intimacy with Mr Derrick, a man of literary pursuits, and well known in the city, he was by him introduced to its novelties and gaieties, in all their variety. At this time, swayed by inclination, and in love with a London life, he wished to obtain a commission in the guards, but his father having signified his disapprobation, he relinquished the design, returned to Edinburgh, and resumed the study of the law.

In 1763, when in London, on his way to the continent, he was first introduced to Dr Johnson, with whom he afterwards spent so much of his time, and with whose name his own has been since so closely associated. On his arrival on the continent he made some stay in Holland and Flanders; he traversed a considerable part of Germany; passed through Switzerland to Geneva; over the Alps to Italy, and thence to Corsica; he returned home in 1766, and commenced his career as a counsellor at the Scotch bar. The Douglas cause, then pending, having excited a general interest, he drew up and published a popular view of the respective claims of both the parties, which he entitled, *The Essence of the Douglas cause.* In 1768, he published *his Account of Corsica, and his Memoirs of General Paoli,* a work which was highly commended by Johnson, and very acceptable to the public. In the following year his happiness was enhanced by his marriage with Miss Margaret Montgomery, his own cousin. From this time he passed a series of years amid the comforts of domestic and social life. He lived in terms of the closest intimacy with the most eminent characters of the age both for rank and literature, among whom were Lords Kames and Hailes, Drs Robertson and Blair. In 1773, he and Johnson made their long projected tour to the Hebrides, a journey which has been rendered memorable by means of the lively and characteristic accounts which both have published of it.

From the period in which Boswell had read the Spectator he had felt and cherished a strong predilection for the manners of England, and this feeling was strengthened by the friendships which he formed with some of the gentlemen from the southern part of the island, whom he met while a student at Glasgow college, as well as in his frequent visits to the metropolis; and having lately succeeded to his father's fortune, which was sufficiently ample to warrant his design, he resolved to gratify his inclination by settling finally in London, a scheme which he carried into effect in the year 1786. The remainder of his life was spent chiefly in London, where he died of a lingering illness on the 19th of June 1795. Dr Johnson paid the debt of nature in December 1784, and Boswell's account of his life appeared in two thick quarto volumes in 1790. It is presumed that there are few English readers who have not perused and have been pleased and instructed with this work. The constant obtrusion of the author and his affairs—all that he was, or is, or would be—on the reader's attention, though at first provoking to disgust or contempt, soon becomes highly amusing, and constitutes a principal part of the entertainment. The numerous anecdotes of persons and events which it contains, serves in many instances to illustrate the literary history of the period it includes. The preservation of so many of the opinions and sentiments of Johnson in his own language, both on subjects with which his studies had made him familiar, as well as on those to which it was not suspected he had bestowed any portion of his attention, displays the strength and the extent of his powers, and forms at the same time a valuable repository of critical, moral, and political maxims and rules. And still more, the dramatic form in which so large a portion of it is cast, and so well sustained, gives an impressive reality to the scenes which it exhibits,—presents a finished picture of the domestic manners of the age to which it belongs,—and affords an exquisite gratification to that gossiping curiosity which seems inherent in human nature.

Thus, though Boswell's life of Johnson cannot be recommended as a model of biographical composition, and never can be generally imitated; because the suspicion of a person haunting social scenes, watching and writing down with the view of publishing whatever is said or done in the most unguarded moments of life, would soon destroy *the play of fancy and the flow of soul,* and introduce into conversation, study, and stiffness, and hypocrisy; and because few will be found inclined, or qualified to undertake the task of following, and observing, and recording the ordinary discourse and private behaviour of any man, in order to enable them to detail the particulars of his conduct, and to delineate the features of his character; yet, as often as a Johnson appears on the stage of life, it is devoutly to be wished, that, with this intention, he may be attended by a patient, a persevering, and an admiring Boswell.

BOTANY.

Introduction.

Introduction.

Botany, from a Greek word, which signifies *herb*, or *grass*, is that department of natural history by which plants are distinguished from each other and systematically arranged; but, in a more enlarged sense, it includes also a knowledge of the structure and functions of vegetables, as well as of their properties and uses.

The vegetable kingdom, which consists of more than 30,000 species, is divided, according to the system of Linnæus, into 24 classes; each class is subdivided into orders, and each order is again subdivided into genera and species. The classification of Linnæus is confessedly artificial; but it is by far the simplest and most convenient yet proposed for studying botany; and those who have made objections to this system, have forgotten, that its object is to distinguish plants from each other with precision, rather than to associate them according to their natural alliances. In all attempts to arrange and classify the objects of nature, it ought to be recollected, that it is for the purpose of assisting the limited powers of man in his investigations; and the more numerous any class of objects becomes, the more necessary it is to adopt method and arrangement in acquiring the knowledge of their distinctive properties. The books of a library, composed of many thousands of volumes on different subjects and in different languages, could not be easily found out if they were promiscuously placed in the shelves; but if they are arranged according to certain rules or principles, such as the subjects on which they treat, the language in which they are written, or even the form or size, the place in which they are deposited can be easily discovered. The amount of a sum of money, consisting of different kinds of coin, as copper, silver, and gold, thrown together into a heap, may be known by reckoning the number and value of each individual piece as it comes to hand; but the knowledge of the value of the whole will be more easily obtained, by arranging the different pieces according to the kind and value of each. All this, it must be admitted, is an artificial procedure; but it is quite obvious that it greatly abridges labour and facilitates investigation.

The characters of the classes in the Linnæan system are taken from certain parts within the flower. In the common primrose, or single polyanthus, the yellow part in the one, and the red in the other, is called the *corolla;* and the green part, which is a continuation of the covering of the stem, is called the cup, or *calyx*, from its shape. Separate the corolla from the calyx, and open the tube of the corolla with a pointed knife, and several threads or filaments attached to its inner surface, and supporting roundish bodies of a yellowish colour, will appear; these are called *stamina*, or *stamens*. Some of the classes are determined by the number of stamens; in this flower the number is five, denoting that it belongs to the fifth class. The flower of the crocus, examined in the same way, presents three stamens, shewing that it is arranged in the third class. Six stamens appear within the flower of the tulip, from which it takes its place in the sixth class; to which also belong the white and orange-lily, the snowdrop, and hyacinth. In the common pink are ten stamens, which point out its place in the tenth class.

Linnæan Classification.

The stamens in some of the flowers now mentioned, derive their origin from the inner surface of the flower, and when the flower is drawn out of the cup they come along with it; but when the six petals of the tulip are broken off, the stamens remain behind; and when these stamens are carefully removed, another part rising from the middle of the seed-vessel appears. This is called style or pistil; and from the number of pistils the orders are determined; as the tulip, in which there is one pistil, belongs to the first order. In the pink there are two pistils, and it belongs to the second order of its class. The characters of the genus are usually derived from the other parts of the flower, and those of the species are taken either from some peculiarity in the parts of fructification, or from the leaves, stem, or root. But, to be able to discriminate plants with facility and accuracy, it is necessary that the student of botany be familiar with the language which is employed, and be well acquainted with those parts on which the character of the classes, and their subordinate divisions, depend.

Chap. I. Principles of the Linnæan Classification.

The characters of the classes and orders of the Linnæan system are taken from the parts of fructification; those of the genera from the same parts, and those of the species from the leaves, stems, and roots.

Sect. I. *Parts of Fructification.*

The parts of fructification, as they are described by Linnæus, are seven in number; and as some of these parts are wanting in some plants, they are not all essentially necessary to the perfection of the seed or fruit. The seven parts are, the calyx or cup, the corolla or flower, the stamina or stamens, the pistillum or pistil, the pericarpium or seed-vessel, the seed, and the receptaculum or receptacle.

Linnæan Classification.

Calyx.—Several varieties of calyx are described; it is called perianthium, or perianth, when it includes the other parts of the flower, as in the primrose and the pink; but it is sometimes wanting, as in the tulip, in some cases permanent till the fruit is ripe, and in others it drops off before the flower is expanded; in mallow it is double, and in scabious it is triple. The *involucrum* is a kind of calyx peculiar to umbelliferous plants; and it is either partial or general, as it includes the whole or only a part of the umbel. The amentum or catkin is a common receptacle, furnished with scales, each of which includes the parts of fructification, and the whole forms an aggregate flower. The willow and the fir tribes furnish examples of the catkin. The *spatha*, or sheath, is a kind of calyx which appears in the snowdrop and the narcissus. The *gluma* or *glume* is the calyx peculiar to grasses, and it is of a chaffy texture.

Corolla.—The corolla is included within the calyx, and usually exhibits those rich and beautiful colours which are so much admired in plants. When the corolla consists of different parts, they are called petals; it consists sometimes of one petal, and then it is said to be monopetalous, as in the primrose; and when it consists of many petals, it is called polypetalous, as in the rose.

A monopetalous corolla is divided into two parts; the tube, or cylindrical part, included in the calyx, and the limb, *limbus*, which is spread out, as in the primrose. When the corolla consists of many petals, as in the pink, that part of it which appears without the calyx is called the border, or *lamina*, and that part inclosed in the calyx is denominated *unguis*, or claw. The corolla is said to be regular or irregular, equal or unequal, when its figure is uniform or otherwise, and the parts of which it is composed are of the same or of a different size.

The more common forms of a monopetalous corolla are the following: Bell-shaped, *campanulata*, as in campanula and hyacinth; funnel-shaped, *infundibuliformis*, as in pulmonaria or lungwort; salver-shaped *hypocrateriformis*, as in the primrose; wheel-shaped, *rotata*, which is the same as salver-shaped, but with scarcely any tube, as in borage; ringent, *ringens*, irregular and gaping, formerly called labiated or lipped, as in dead-nettle; and personate, *personata*, irregular, and closed by a kind of palate, as in snapdragon.

The polypetalous corolla is called cruciform, *cruciformis*, when the petals are disposed in the form of a cross, as in wallflower; rosaceous, *rosacea*, when the petals are disposed like a rose; papilionaceous, *papilionacea*, when they are irregular and spreading, and have the appearance of a butterfly.

The corolla is said to be incomplete when some parts seem wanting; and in some cases it is altogether wanting, although a diversity of opinion prevails whether the calyx, which is present in some of these cases, should not be considered as such.

Nectary.—The nectary, *nectarium*, is generally connected with the corolla, or forms part of it; the nectary is distinct from the petals of the corolla in columbine, and it is an elongation of the corolla in the violet, and a production of the calyx in Indian cress. Larkspur and monkshood furnish striking examples of the nectary in the spur-like appendages of their flowers; and a small gland at the base of the petals of some flowers, as the ranunculus, comes under the same denomination. The use assigned to the nectary is the secretion of honey.

Stamens.—The stamens are placed within the corolla, and vary in number in different flowers. A stamen consists of two parts, the filament and anther. In the pink the filament is slender, and in the orange-lily and tulip it is strong and thick; in some plants it is wanting; but where the filament exists it supports the anther, which is a membranous body, consisting generally of two cells or cavities. The pollen, or fine powder, is prepared in the anther, which either bursts longitudinally or opens by pores near the summit. The pollen, when examined with the microscope, exhibits great variety of form and structure in different plants.

Pistil.—The pistil is that part which arises from the centre of the flower; it is composed of three parts, the stigma, the style, and the germen. The stigma, which is the upper part of the pistil, is various in form, either simple, scarcely more than a point, globular, lobed, hollow, and gaping. The length and thickness of the style are various, but it is sometimes entirely wanting. The germen, which gives origin to the style and stigma, is also various in its form and size; sometimes it is included between the calyx and corolla, and then it is said to be superior, as in the strawberry and raspberry, and inferior, as in the apple and pear.

Pericarp.—The pericarp, *pericarpium*, or seed-vessel, is the enlarged germen or covering of the seed. It is not an essential part of every plant, for in some it is wanting, as in the dead-nettle, in which the seeds are naked in the bottom of the calyx; and in the common dandelion, and many plants of the same kind, the seeds are attached to the receptacle without any covering.

Various kinds of seed-vessels are described, as the capsule, which is of a leathery or membranous texture, composed of one or several cells, as in campanula and poppy. The follicle is a seed-vessel of one valve and one cell, bursting lengthwise, and bearing the seeds near its edges, as in periwinkle and pæony. The silique, *siliqua*, is a long dry seed-vessel of two valves, as in stock jilly-flower. The silicle is a short round pod, as in vernal whitlow grass. The legume, *legumen*, is a seed-vessel of two oblong valves, and is peculiar to the pea tribe. The tamarind produces a legume filled with pulp, in which the seeds are imbedded. The drupe, *drupa*, is the seed-vessel peculiar to stone fruit, has a fleshy coat, and contains a single hard and bony nut, as in the cherry, the plum, and the peach. The cocoa-nut also comes under the denomination of drupe. The pomum or apple has a fleshy coat, but includes a capsule, with several seeds, as in the common apple or pear. The berry, *bacca*, is fleshy, without valves, and contains one or more seeds, surrounded with pulp, as in deadly nightshade and ivy. The fruit of the raspberry and bramble is called a compound berry, and the separated parts are named *acini*. Strobilus or cone, is a catkin, hardened and enlarged into a seed-vessel, examples of which are found in the pine tribe.

The seeds are extremely various in form and size; they are composed of the embryo or germ; of cotyledons or seed-lobes; the *albumen* or farinaceous part; the *vitellus* or yoke; the testa, which contains the different parts of the seed; and the *hilum*, or scar, by which the seed is attached to the seed-vessel. The pellicle, or epidermis, adheres closely to the outside of some seeds; and the arillus, or tunic, is either a complete or partial covering attached to the base only, and surrounding the other parts more or less loosely. Some seeds are furnished with a pappus or down, which is chaffy, feathery, or bristly. The seeds of dandelion afford an example of the feathery structure. Seeds are also furnished with a tail, with a beak, or with wings.

The receptacle, *receptaculum*, is the common point of connection of all the other parts of fructification. It is called the receptacle of the flower, when the calyx, corolla, and stamens, only are attached to it. It is denominated a *proper* receptacle, when only one flower with its fruit is inserted into it,—and *common*, when it supports many flowers. In such as are called compound, it is very distinct, as in the daisy, where it is of a conical form; in others, it is convex, flat, or concave; and in some it is naked, hairy, scaly, or cellular, like a honey-comb.

Sect. II. *Of the Classes and Orders.*

The Linnæan system of botany includes 24 classes, the characters of which are derived from the number, situation, and proportion of the stamens. The first eleven classes are determined by the number of the stamens, and the names by which they are distinguished, derived from the Greek language, are characteristic of this mode of discrimination.

The 1st class, *Monandria*, signifies that the plants included under it have only one stamen. The 2d, class, *Diandria*, indicates two stamens; the 3d, *Triandria*, three stamens; 4th, *Tetrandria*, four stamens; 5th, *Pentandria*, five stamens; 6th, *Hexandria*, six stamens; 7th, *Heptandria*, seven stamens; 8th, *Octandria*, eight stamens; 9th, *Enneandria*, nine stamens; 10th, *Decandria*, ten stamens; 11th, *Dodecandria*, from 12 to 19 stamens; 12th, *Icosandria*, 20 or more stamens; and, 13th, *Polyandria*, in which the stamens are very numerous. But, in the two last classes, the situation of the stamens must be taken into consideration. When they arise from the inside of the calyx of plants they belong to the class Icosandria, as in the strawberry and bramble, the cherry and the myrtle; but when they are inserted into the receptacle or base of the flower, they fall under the class Polyandria, of which the poppy and anemone are good examples.

The 14th class, *Didynamia*, is distinguished by the proportion in the length of the stamens, which are four in number, two of which are long and two short. This is justly reckoned a natural class, for it includes plants which exhibit the same general character in the structure of their flowers, to which the denomination ringent or personate has been applied. The dead-nettle, foxglove, and snapdragon are examples.

The 15th class, *Tetradynamia*, is also a natural class, and is distinguished by four long and two short stamens; the flowers of this class are called cruciform, because the four petals of the corolla are set in opposition to each other in the form of a cross, as wallflower, radish, and mustard.

In the 16th class, *Monadelphia*, the stamens are united by their filaments into a tube, as is distinctly seen in mallow and lavatera, and less obvious in the numerous family of geranium.

The 17th class, *Diadelphia*, has the stamens united by their filaments in two parcels; and it is a natural class, for it consists of papilionaceous flowers, of which the flowers of the pea tribe are examples.

The 18th class, *Polyadelphia*, includes such plants as have the stamens united by the filaments into more than two parcels, as in St Johnswort.

In the 19th class, *Syngenesia*, the stamens are united by their anthers into a tube, and the flowers of this class are compound, that is, a number of flowers is collected together within the same calyx, or upon the same receptacle, of which the common daisy, dandelion, and sun-flower furnish appropriate examples.

The 20th class, *Gynandria*, is characterised by the stamens growing out of the pistil, or being united with it, of which examples are found in the orchis tribe.

The 21st class, *Monœcia*, signifying one house, includes those plants which have stamens and pistils in separate flowers, but growing on the same plant, as in the oak and hazel.

In the 22d class, *Diœcia*, which signifies two houses, the stamens and pistils are not only in separate flowers, but the flowers which produce stamens, and those which produce pistils, grow on separate plants, as in the hop, the willow, and yew.

The 23d class, *Polygamia*, comprehends such plants as have stamens and pistils separate in some flowers and united in others, either on the same plant or on two or three different plants, as in pellitory, and sea-purslane.

The 24th class, *Cryptogamia*, includes those plants in which the parts of fructification are not distinctly ascertained, and therefore cannot be referred to any of the preceding classes Ferns, mosses, and sea-weeds are examples of this class.

The *Palmæ*, palm-trees, from their peculiarity of structure and appearance, were described by Linnæus in an appendix to the twenty-four classes; but it appears, from the researches and observations of succeeding botanists, that they may be arranged under the Hexandria, or 6th class, or under Monœcia, or Diœcia, the 21st or 22d class.

Orders.—In the first 12 classes of the Linnæan system, the orders are determined by the number of pistils, and the Greek words, *Monogynia*, *Digynia*, *Trigynia*, denote one, two, or three pistils. The number of pistils is reckoned by the styles, or, when the style is wanting, by the number of stigmas, as in the gelder-rose; and the number of pistils expressed by the Greek numerals marks the order, as *Monogynia*, having one pistil, denotes the first order, *Digynia*, *Trigynia*, *Tetragynia*, *Pentagynia*, *Hexagynia*, *Heptagynia*, *Decagynia*, *Dodecagynia*, expressive of two, three, four, five, six, seven, ten, and twelve pistils, and

Polygynia, signifying many pistils, all refer to corresponding orders of the class in which such plants occur.

Didynamia, the 14th class, contains two orders: 1. *Gymnospermia*, so denominated from the seeds being naked, or uncovered, and they are almost always four in number, as in the dead-nettle; 2. *Angiospermia*, expressive of the seeds, which are numerous, being included in a capsule, or seed-vessel, as in foxglove and snapdragon.

Tetradynamia, the 15th class, has also two orders, which are determined by the form of the fruit: 1. *Siliculosa*, in which the fruit is a silicle, or roundish pod, as in shepherds-purse, and the common garden-cress; and, 2. *Siliquosa*, in which the fruit is a siliqua, or long pod, as in the pea tribe.

In the 16th, 17th, and 18th classes, Monadelphia, Diadelphia, Polyadelphia, the characters of the orders are taken from the number of the stamens, as in the first thirteen classes.

Syngenesia, the 19th class, comprehends five orders, the characters of which are taken from the florets, of which the compound flower is formed, being united or separated, barren, fertile, or abortive.

The first order, *Polygamia æqualis*, includes those plants in which all the florets have both stamens and pistils, and produce seeds, as in dandelion. 2. *Polygamia superflua*, in which the flowers consist of two parts, a disk, or central part, and radii, or rays, which project outward; the florets of the disk have stamens and pistil, and those of the rays have pistil only, but each of them produces perfect seed, as in the daisy, chamomile, and corn-marygold. 3. *Polygamia frustranea*, in which the florets of the disk have stamens and pistil, but those of the rays have only an abortive pistil, as in blue-bottle. 4. *Polygamia necessaria*, in which the florets of the disk are furnished with stamens only, and those of the radius with pistils only, as in garden-marygold. 5. *Polygamia segregata*, in which each of the florets has a proper calyx included in one general calyx, as in *echinops*, or globe-thistle. To this class Linnæus added a sixth order, *Monogamia*, in which the flowers are not compound, but single, as the word denotes; but as the union of the anthers is not always uniform, the plants belonging to this order have been arranged by later botanists under other classes, according to the number of stamens.

In the 20th, 21st, and 22d classes the orders are formed from the number of stamens, or from the character of some of the preceding classes.

Polygamia, the 23d class, includes three orders, formed upon the principles of the classes immediately preceding. 1. *Monœcia*, in which flowers with both stamens and pistils, or flowers with pistils or stamens only, grow on the same plant. 2. *Diœcia*, when two or three kinds of flowers appear on two separate plants. 3. *Triœcia*, in which the different flowers just described grow on three separate plants, of which the fig furnishes an example.

The 24th class, *Cryptogamia*, was divided by Linnæus into four orders, namely, ferns, mosses, flags, and mushrooms; but Dr Smith has added a fifth order. 1. *Filices*, or ferns, in which the fructification appears on the back, summit, or near the base of the leaf, which is denominated a frond. 2. *Musci*, or mosses, which have separate leaves, and often a stem, and are furnished with a calyptra, or hood-like corolla. 3. *Hepaticæ*, or liverworts, having the leaf and stem united, forming a frond, but the capsules do not open with a lid as in the mosses. In the 4th order, *Algæ*, or flags, the herb is a frond, and the seeds are imbedded in its substance, or in the disk of a peculiar receptacle. 5. *Fungi*, or mushrooms, have no leaves, and the fructification is in a fleshy substance.

Sect. III. *Of Genera and Species.*

The orders are again subdivided into genera. The characteristic marks of the genera are derived from the flowers and fruit, and a genus comprehends one or more species, which resemble each other in some parts of the flower or fruit, or of both. Three kinds of generic characters are mentioned by Linnæus, the factitious, essential, and the natural, all depending on the fructification alone, and not on the inflorescence or on any other part: by the factitious character, genera that come together in the same artificial order, or section, are discriminated; by the essential character, a particular genus is distinguished by one striking mark from all genera of the same natural order, and, consequently, from all other plants; and the natural characters include all the marks common to all the species of the genus. The natural character of genera is employed by Linnæus in his *Genera Plantarum;* but to this method of discrimination it has been objected, that it does not direct the mind to the most important marks, and that it only accords with such species of the genus as are known to the author, from which it is obviously imperfect; but the essential character, which is now universally adopted to distinguish genera, comprehends all the marks necessary to discriminate each genus from every other in the system.

The characters which are employed in distinguishing species should be constructed on the same principles as the characters of the genera, and they ought to be certain, clear, and concise. No characters ought to be adopted in the discrimination of the species which have been already enumerated among the generic marks. For the sake of brevity, Linnæus limited his specific definitions to twelve words, a rule which has been followed by succeeding naturalists, especially those who have employed the Latin language, in which it is most practicable.

In the construction of generic and specific characters, the arrangement of the different parts from which these marks are derived ought to be attended to. The most important in the natural order, or genus, are first mentioned, and the subordinate, or more particular marks of the object to which they are applied, ought to conclude the description; but in drawing up the natural characters of a genus, the calyx, corolla, stamens, pistils, seed-vessel, seed, and receptacle, are to be described in their order; and the root, stem, leaves, appendages, flower, and fruit, point out the arrangement, when a full description of any particular plant is required.

Of Sections.—The labour of research is greatly abridged and facilitated by associating together such genera and species as are allied by certain marks.

Such groups of genera and species are distributed into sections; and each section being particularly characterised, if it shall appear that the plant possesses the character of that section, after the class and order have been ascertained, and the genus to which it belongs is sought for, it is only necessary to compare it with the descriptions comprehended under that particular section. Thus the position of the germen furnishes marks for the formation of two sections in certain genera, which are characterised by having the flower superior or inferior, as when the receptacle of the flower is above the germen it is called superior, and when the receptacle is below the germen it is called inferior. The number of petals furnishes discriminative marks for the division of the genera of the 13th class into sections. In the 14th class, *Didynamia*, the character of the sections is derived from the calyx, which is said to be two-lipped, or bilabiated, when the mouth resembles two lips, and cleft when it is divided into so many parts. The pod being notched at the point, or being entire, in the first order of the 15th class, is the foundation of two sections; and the calyx being closed or open, affords characters for the two sections into which the second order is divided. The first order of the fourth class, in Smith's *Flora Britannica*, exhibits a good illustration of this division into sections. This order consists of five sections: In the first the flowers are monopetalous, one-seeded, and superior; in the second, they are monopetalous, two-seeded, and superior; in the third section the flowers are monopetalous, many-seeded, and inferior; in the fourth section the corolla has four petals; and in the fifth the flowers are apetalous, or want the corolla. An example of the distribution of the species belonging to the genus veronica, or speedwell, may be taken from the same work. This genus is divided into three sections, including, first, those species which have flowers in a spike; second, those whose flowers grow in clusters; and, third, those which have solitary flowers.

Sect. IV. *Method of investigating the Class, Order, &c. of a Plant.*

The principles of the Linnæan classification being distinctly understood, the examination of plants, for the purpose of ascertaining to what class, order, genus, and species they belong, is next to be attempted. Flowers in different states, some that are expanded, some not yet unfolded, and some which have ripened their fruit or seed, should be selected; and, in determining the class, the number, situation, proportion, or connection of the stamens, is to be considered. To assist the student in determining this point, reference may be made to Plate 28. in which the Roman numerals mark the classes. Fig. 1. represents one stamen inserted at the base of the germen. 2. Two stamens attached to the tube of the corolla. 3. Two stamens rising from the tube of the corolla. 4. Three stamens rising from the tube. 5. A B, a glume; C D, the chaff; D E, one of the valves of the chaff, terminated by an awn, three stamens with anthers bifid at the two extremities. 6. Four sessile anthers attached to the orifice of the corolla. 7. Four stamens rising out of it. 8. Five stamens alternating with the petals. 9. Five stamens opposite to the divisions of the corolla. 10. Five stamens with arrow-headed anthers attached to the corolla. 11. Six stamens alternating with the divisions of the perianth. 12. and 13. Six stamens with sessile anthers attached to the orifice of a globular perianth; A, is a limb with six teeth. 14. Seven stamens. 15. A spurred calyx; five petals with long claws. 16. Eight stamens; the germen central. 17. A calyx with three small leaves, the corolla with three petals, stamens nine. 18. The germen surrounded with nine stamens. 19. A monophyllous calyx calyculated, or with a small calyx at its base, and five petals. 20. Ten stamens supported on a cylindrical disk proceeding from the bottom of the calyx of Fig. 19. 21. Monophyllous calyx, five petals with two lobed laminæ and ten stamens. 22. Twelve stamens with double anthers and pedicellated germen. 23. Twelve stamens proceeding from a simple monophyllous perianth, the limb three-lobed. 24. The same perianth opened lengthwise. 25. A corolla with five petals, the stamens numerous. 26. A compound berry. 27. The stamens inserted on the calyx. 28. Stamens inserted at the orifice of the perianth, the germen globular, the style short, and the stigma rounded. 29. A flower with five petals and a great number of stamens. 30. Calyx of the flower, Fig. 29. separated from its petals, to shew the attachment of the stamens below the germen. 31. B, the part where the leaves of the calyx, the petals, and the stamens, were attached; A, many germens united into one head. 32. B, one-lipped corolla, the stamens didynamious; A, two-lipped corolla, the stamens didynamious, or two long and two short. 33. The calyx divided lengthwise, shewing a germen with four lobes becoming four small seeds, the styles slender, with a bifid stigma. 34. An irregular two-lipped corolla, with a spur. 35. The same opened lengthwise, to shew the didynamious stamens. 36. The capsule cut transversely, to shew the two cells and the seeds. 37. Tetradynamious stamens, or four long and two short, surrounding a slender pistil, surmounted by a stigma notched at the top. 38. A cruciform flower. 39. A silique, *siliqua*, or long pod. 40. Another cruciform flower. 41. Silicle, or short pod open. 42. Stamens united together in the class Monadelphia. 43. Corolla, with five petals notched at their summits. 44. The fruit divided into five small capsules, each surmounted by a part of the style which is permanent. 45. Ten stamens, of which nine are united and one is separated, indicating the class Diadelphia. 46. and 47. Papilionaceous flowers. 48. A legume, or pod of the pea tribe. 49. A corolla with five petals, the stamens united in three parcels, A B C, as in the class Polyadelphia. 50. A B C, a floret; A, the stamens united by the anthers, the character of the Syngenesia class; B, the tubulated perianth formed of the petals; C, feathered seeds. 51. A, The style coming from the tube of the united anthers; C, the limb lengthened into a strap called a ligulated flower. 52. A compound, radiated, or rayed flower. 53. A, An involucrum, or common calyx; B, a common receptacle; C, feathered seeds; E, the down; D, the foot stalks. 54. A simple irregular perianth, attached by its base to the germen;

B, the germen; A, six sessile anthers fixed on the style, denoting the class Gynandria. 55. An irregular polypetalous flower, with the anthers united by the filaments. 56. A monœcious plant; A, the flowers with stamens, and B, the flowers with pistils, both growing on the same plant. 57. A, Flower with stamens; B, Flower with pistils. 58. A, Flower with stamens; B, Flower with pistils. 59. A, Flower with stamens; B, Flower with pistils; and C, Flower with both stamens and pistils, on the same or different plants. 60. A moss. 61. A mushroom.

Inflorescence.—The inflorescence, or mode of flowering, that is, the distribution of the flowers on plants, afford useful discriminating marks; and of these, different kinds have received appropriate names.

When the flowers surround the stem in a kind of ring, it is called *verticillus*, or whorl, as in dead-nettle and wild marjoram.

A cluster, or raceme, *racemus*, is composed of numerous rather distant flowers, each having its own proper stalk, but all arising from a common stalk, as in red currants. *Solanum dulcamara*, bitter-sweet, exhibits an example of a compound raceme; and *actæa racemosa* produces an aggregate raceme, where several are collected together.

The spike, *spica*, is characterised by numerous flowers on a common stalk, without partial stalks, as in broad-leaved plantain. Sometimes the spike is compound, as in *lavandula pinnata;* and when the flowers are all on one side, it is called *spica secunda.* A spicula, or spikelet, is applied to the grasses which have many florets in one calyx, as in *poa aquatica.*

Corymbus, or corymb, is a spike with partial flower-stalks, gradually longer as they are lower on the common stalk, so that all the flowers are nearly on a level, as in the common cabbage, which becomes a raceme when it is in fruit.

Fasciculus, or fascicle, is applied to flowers which have little stalks variously inserted and subdivided, but collected into a close bundle, which is level at the top, of which common sweetwilliam is a good example.

Capitulum, a head or tuft, has sessile flowers arranged in a globular form, as in sea-pink and globe-amaranthus.

Umbella, or umbel, has several flower-stalks or rays, nearly of equal length, rising from a common centre, and the summits forming a level, convex, rounded, and rarely a concave surface. It is called a simple umbel when each ray has a single flower, and compound when each stalk or ray supports a small or partial umbel. This peculiar distribution of the flowers is the origin of the name of a natural order of plants, which are thus denominated *umbellated*, or *umbelliferous*, as the common carrot, parsley, and hemlock.

Cyma, or *cyme*, agreeing in general appearance with the umbel, has the stalks arising from one centre, but variously and alternately subdivided, as in the common laurus-tinus and elder.

Panicula or *panicle*, has the flowers in a loose subdivided bunch or cluster, without order. When the stalks are distant, it is called a spreading panicle, as in London-pride, *saxifraga umbrosa*, and in the common cultivated oat. When the panicle is more crowded it is called dense or close, and when more spreading, it is said to be divaricated.

Thyrsus, a bunch, is a dense or close panicle, approaching to an ovate form, as in the common lilac; *tussilago petasites*, or common butter bur, is also an example of the thyrsus.

Stems.—A flower-stalk is said to be solitary when it bears one flower, clustered, in which several stems are united together; radical, when they arise from the root; cauline, when they spring from the stem; axillary, when they grow from the axillæ of the leaves; and lateral, or terminal, as they proceed from the side or extremity of the stem.

Culmus, Culm, or Straw, is the stem peculiar to the grasses, rushes, and similar plants. It is either without joints, as in the common rush; jointed, as in most of the grasses; geniculated, or kneed, as in a common species of fox-tail grass.

Scapus, or stalk, is that stem which springs from the root, and supports the flower and seed, but not the leaves, as in the common primrose.

Pedunculus, is the flower-stalk which springs from the stem, and supports the flowers and fruit, but not the leaves.

Petiolus, or petiole, is the foot-stalk of the leaf, and is a term exclusively appropriated to leaves; and it is either simple or compound, as it supports one or more leaves.

Frons, or frond, is a term applied to the leaves of ferns, in which the stem, leaf, and parts of fructification are united.

Stipes, or stipe, is the term applied to the stem of a frond, and to the stalk of a mushroom; the stipes in ferns is commonly scaly.

Leaves.—In the description of plants, and particularly in the discrimination of species, the forms of leaves afford obvious characters, and therefore merit attention. Leaves are properly distinguished into simple and compound. Plate 29. exhibits a view of the forms of simple leaves; Fig. 1. is an elliptical leaf; 2. an oval pointed leaf; 3. an oval reversed; 4. oblong; 5. linear and lance-shaped; 6. awl-shaped; 7. thick linear; 8. linear; 9. arrow-headed; 10. triangular; 11. crescent-shaped; 12. kidney-formed; 13. round kidney-formed; 14. rounded and crenulated; 15. five lobed; 16. four lobed; 17. three lobed; 18. heart-shaped reversed; 19. halbert-shaped; 20. arrow-headed and blunt at the summit; 21. runcinated; 22. with seven or eight toothed lobes; 23. seven lobed with two small ears, rounded at the base; 24. with five divisions nearly palmated; 25. trifid and bitten; 26. with five divisions, palmated; 27. oblong, crenulated, and wrinkled; 28. rounded, with nine lobes not deep, and toothed; 29. plaited, with seven toothed lobes; 30. seven lobed; 31. sinuated and toothed; 32. lance-shaped, and serrated, or toothed like a saw; 33. heart-shaped, oval, and serrated; 34. cylindrical and fistulous, or hollow; 35. rounded, oval, and doubly toothed; 36. palmated, the divisions notched at the summit; 37. rounded, oval, toothed; 38. rounded, elliptical, crenulated; 39. a, slightly sinuated, b, sinuated; 40. heart-shaped, serrated; 41. oblong, oval, serrated; 42. rounded, sinuated, peltated; 43. round, peltated; 44. lyre-shaped, or lyrated; 45. notched at the summit; 46. oval, bifid at the sum-

Linnæan Classification.

mit; 47. oval, pointed; 48. petiolated, rounded, heart-shaped, and dotted; 49. oval, lance-shaped, slightly sinuated; 50. three-cornered, pyramidal; 51. heart-shaped, pointed; 52. oval, five-nerved; 53. pointed, oval, three-nerved; 54. oblong, lance-shaped, half embracing the stalk; 55. fleshy, linear, cylindrical, and rough with points; 56. divided into five segments; 57. dotted, succulent, spatulated; 58. fiddle-shaped; 59. halbert-shaped, and double-eared; 60. angular, equally sinuated; 61. united; 62. elliptical, oval, crenulated; 63. arrow headed, triangular, bitten; 64. rhomboidal; 65. oblong, with two small pointed ears on the foot stalk; 66. pinnatifid; 67. arrow-headed, embracing; 68. perfoliated, sharp, oval; 69. long linear, sheathing at the base, a, b, the sheath.

Plate 30. presents a view of the forms of compound leaves: Figure 1. a leaf composed of four oval serrated leaves; 2. three reversed oval leaves, toothed; 3. two opposite leaves; 4. five-fingered serrated leaf; 5. nine digitated leaflets, oval, lance shaped, and serrated; 6. five reversed, oval, and serrated leaflets; 7. pennatiform, interrupted, with the pinnæ serrated; 8. pinnated, with an odd leaf, the pinnæ opposite; 9. eight lance-shaped pinnæ, serrated, and pedated; 10. pinnated, without an odd one, the pinnæ alternate; 11. pinnated without an odd one, the pinnæ opposite; 12. pinnated, with an odd one, the pinnæ alternate; 13. a winged stem, articulated, with sessile leaves at the articulations; 14. with opposite lance-shaped pinnæ, the foot-stalk terminating in a tendril; the stipulae arrow-headed; 15. pinnated, with opposite pinnæ, and terminated by a tendril; 16. with six pinnæ, without an odd one, the common foot-stalk winged; 17. twice pinnated, with heart-shaped pinnæ; 18. twice pinnated, with unequal pinnæ; 19. twice pinnated, without an odd leaflet; 20. triply pinnated; 21. triply pinnated, with an odd leaflet; 22. triply pinnated, with an odd leaflet, with pointed oval pinnæ; 23. a decompounded leaf.

Roots.—Roots sometimes afford specific names to plants, so that their forms and diversities require attention in descriptions.

A fibrous root, *radix fibrosa*, is the simplest kind, and is composed of fibres which are either undivided or branched. This kind of root is peculiar to many grasses, and to most annual plants.

A creeping root, *radix repens*, is considered as a kind of underground stem, which shoots out horizontally, and throws off fibres in its course. Couch-grass, and the common bent on sand hills near the sea, are excellent examples of this kind of root, to which may be added common mint.

A fusiform, or spindle shaped root, *radix fusiformis*, is of a tapering form, and penetrates perpendicularly into the ground, as in the carrot, the parsnip, and radish.

An abrupt root, *radix præmorsa*, has somewhat of a spindle-shape, but it is abrupt or bitten off at its extremity, as in *scabiosa succisa*, devils bit scabious.

A tuberous or knobbed root, *radix tuberosa*, is composed of fleshy knobs, connected by common stalks or fibres, as in *solanum tuberosum*, the potatoe, and *helianthus tuberosus*, or Jerusalem artichoke.

A bulbous root, *radix bulbosa*, is either solid, as in the crocus,—or composed of concentrical layers, as in the onion,—or scaly, consisting of fleshy scales attached at the base, as in the white and orange lily.

Monandria.

A jointed or granulated root, *radix articulata*, or *granulata*, is composed of a number of small grains, or fleshy knobs, as in *saxifraga granulata*, white saxifrage, and *oxalis acetosella*, or wood-sorrel.

Chap. II. Illustration of the Classes.

In the selection of examples for illustrating the classification, the preference has been given to such plants as are most common, or most accessible, whether they are found indigenous, cultivated in the garden, or require the shelter of the green-house or stove; in some the choice has been determined by peculiarity of structure or habits, or the valuable uses to which they are applied as food, or in the arts of life; and such notices of their natural history are occasionally introduced, as may enable the student to extend his view of the diversified objects of the vegetable kingdom beyond the limits of mere nomenclature.

Class I. Monandria. One Stamen.

This class includes two orders.

Order I. Monogynia.

In the distribution of the genera belonging to this order, four sections are formed. Sect. 1. contains the natural order called *scitamineæ*, or spicy plants, all which are exotics, and they are distinguished by having the germen inferior, and having one or two cells; sect. 2. germen inferior, and four-celled; sect. 3. germen superior; sect. 4. one-seeded.

Hedychium *Coronarium*, Sweet-scented Garland Flower. *Gen. char.*—Calyx, one-leaved, bursting; tube of corolla very long; limb double, tripartite; nectary two-leaved. This fragrant flower is snow-white, is a native of India, and is much cultivated in the Malaccas; requires the heat of a stove in this country, and is met with in some of the gardens near London.—*Bot. Mag.* 708.

Amomum *Zinziber*, Ginger. *Gen. char.*—Cal. three-cleft, unequal, cylindrical; corolla tripartite, unequal, spreading; nect. two-lipped, and somewhat erect. *Spec. char.*—Scape naked, spike and scales ovate, leaves lance-shaped, and ciliated on the margin near the summit. This plant has something of the habit of a grass in its appearance, and it grows to the height of two, and sometimes three feet; it is a native of the East Indies, and is extensively cultivated in the West Indies, where it is planted in March or April, flowers about September, and, when the stalks have withered about the end of the year, the roots are dug up in January and February following.

The roots of ginger, on account of which it is cultivated, furnish a well known and excellent spice. Two kinds are met with in commerce, the black and the white ginger. They are the roots of the same plant, and differ only in the selection and mode of curing. The larger roots are chosen for the white ginger; and each root being washed and scraped separately, is dried in the sun. The whole of the remaining roots of the crop, after being picked and cleaned, are put into baskets, dipped into boiling water, and after being scalded, are dried on a platform, and put up in bags for the market, under the name of black ginger.

The young roots of ginger constitute one of the most delicious preserves. When intended for this purpose, the roots are dug up while they are tender and full of sap, carefully picked and washed, and after being scraped and peeled, they are put into jars, and covered with syrup, which is sometimes shifted two or three times.

Canna *Indica*, common Indian Reed, or Indian Shot; the first name derived from the appearance of its stem and leaves, and the second from its hard round seeds, resembling lead shot, and employed, it is said, by the Indians for the same purpose; is a native of both the Indies, and is often cultivated in the gardens of Europe on account of the beauty of its foliage and flowers; but it requires artificial heat. *Gen. char.*—Cal. three-leaved; cor. six-parted, erect, with a two-parted revolute lip; style lance-shaped, adhering to the corolla. *Spec. char.*—Leaves ovate, acuminate, and ribbed. Several varieties of this beautiful plant are enumerated, some of which have yellow flowers. Plate 31. Fig. 1.

Salicornia. *Gen. char.*—Cal. entire, ventricose; cor. none; one seed, covered by the calyx.

Sal. *Herbacea*, Jointed Glasswort, or Saltwort. Knees compressed, emarginate, joints obconical, spikes with footstalks, tapering towards the top.

Sal. *Fruticosa*, Shrubby Samphire, or jointed Glasswort; knees round, entire, joints equal, spikes subsessile. Both these species are natives of Britain and grow in salt-marshes near the sea. They flower in August and September, and the first is annual or biennial, and the last perennial.

Hippuris *Vulgaris*, Mare's-tail. *Gen. char.*—Cal. indistinct, entire; cor. none; stigma simple; one seed, inferior. *Spec. char.*—Leaves linear, in whorls. Native of Britain, in ditches and stagnant pools, but not very common. Near Lynn, and other parts of Norfolk, and at the edge of Duddingston-loch near Edinburgh. Perennial, and flowers in May. This plant is easily distinguished by its spreading linear leaves, from eight to twelve in the whorl, and by the single stamen rising from the base of the leaf, or the single seed at a later period of the season.

Order II. Digynia.

Callitriche.—*Gen. char.*—Cal. none; petals two; stigmas acute; seeds four, compressed, naked, margined on one side.

Call. *Aquatica*, Water Starwort; an annual plant, common in the ditches or stagnant waters of Britain; is in flower from April to October, and is easily distinguished by its floating leaves and small white sessile, solitary and axillary flowers. Two species, *verna* and *autumnalis*, have been described; but they are considered as only varieties, the latter of which is distinguished by all the leaves being uniformly linear.

Blitum. *Gen. char.*—Cal. three-cleft; petals none; one seed in a berried calyx.

Blit. *Virgatum*, Strawberry-blite. Little heads, sparse, and growing from the sides of the stem. This species, which is a native of Spain and Tartary, and was first introduced into this country in 1759, is now well known among the hardy annuals of every garden under the name of Strawberry Spinach, a name derived from the beautiful red colour of its berries, and the form of its leaves.

Observ.—It sometimes happens, that a plant, from the parts of fructification that determine the class, should be arranged in a different class from those species with which it agrees in all other respects. To mark the anomaly, and at the same time to retain the plant in its place among those species with which it is naturally allied, Linnæus has ingeniously contrived to introduce it after the generic characters of the order and class to which it belongs. Thus, the genus *Tradescantia* belongs to the sixth class; but one species has only a single stamen, and therefore belongs to the first class, and to the third section of the first order of that class, at the end of which it is set down with its specific name, thus, *Tradescantia monandra*. According to the same plan, *Valeriana rubra*, and *Angustifolia*, have only one stamen and one seed, and are therefore noted at the end of the fourth section of the first order of the first class, but retain their place among the species to which they are naturally allied, in the first order of the third class.

Class II. Diandria. Two Stamens.

This class is divided into three orders.

Order I. Monogynia.

Jasminum, Jasmine. *Gen. char.*—Cor. five-cleft; berry two-seeded; seeds in a seed-coat; anthers within the tube.

Jas. *Officinale*, Common Jasmine; with opposite pinnated leaves, leaflets sharp pointed. The common jasmine, which is a native of Switzerland and India, recommends itself by the beauty of its leaves, and the fragrance of its flowers, and finds a place in every garden.

Jas. *Odoratissimum*, Sweetest Jasmine; with leaves alternate, bluntish, ternate, and pinnated; a native of Madeira, but common in the greenhouses of this country, and displaying its yellow flowers from May to November. The trivial name is far from being appropriate, for it is inferior in fragrance to the common jasmine.

Jas. *Fruticans*, Yellow or Berry-bearing Jasmine; with alternate, ternate, and simple leaves, and angular stems, leaflets ob-ovate; a native of the Levant and the south of Europe; is easily distinguished by the rich green of the foliage, and fine yellow colour of the blossoms, which are succeeded by black berries.

Diandria.

Ligustrum, Privet. *Gen. char.*—Cor. four-cleft; berry superior, two-celled, four-seeded.

Lig. *Vulgare*, Privet, or Prim-print; leaves elliptical, lance-shaped, obtuse, and somewhat dagger-pointed. This beautiful evergreen is a native of Britain and other parts of Europe, and shews its white flowers in May and June, which are succeeded by black berries of a very bitter taste.

Syringa, Lilac. *Gen. char.*—Cor. four-cleft; caps. two-celled.

Syr. *Vulgaris*, Common Lilac; with entire, ovate, heart-shaped leaves. This fine shrub, a native of Persia, is universally cultivated in this country, and is always admired on account of the beauty of its large bunches of blue, violet, or white flowers, which appear in different varieties.

Syr. *Persica*, Persian Lilac; with entire, lance-shaped leaves; is also, as the name indicates, a native of Persia, but is common in the gardens of Europe; is a shrub of humbler growth, and produces a large panicle of flowers of a pale purple colour.

Fraxinus. *Gen. char.*—Cal. none, or four-parted; cor. none, or four-parted; caps. superior, two-celled, leafy above, and compressed; seed solitary, pendulous.

Frax. *Excelsior*, Common Ash-tree; with serrated leaflets, and flowers destitute of calyx and corolla. This lofty tree, which is met with every-where, affords a fine example of pinnated leaves terminated by an odd leaflet, and is remarkable for the lateness of its frondescence, or coming into leaf. It flowers in April and May, and the large dark-purple anthers fall off before the leaves are unfolded.

The variety with pendulous branches, called Weeping ash, is also well known.

Circæa. *Gen. char.*—Cor. two-petaled; cal. two-leaved, superior; caps. two-celled; seed solitary.

Cir. *Lutetiana*, Common Enchanters Nightshade; with erect stem, and leaves ovate, toothed, opaque, pubescent; is common in woods and moist shady places of Britain, and flowers in June and July.

Veronica, Speedwell. *Gen. char.*—Cor. four-cleft, wheel-shaped, the lowest segment narrower; caps. superior, two-celled.

Ver. *Spicata*, Spiked Speedwell; spike terminal, with opposite bluntish-notched serrated leaves, which are very entire at the extremity of the stalk, ascending, and very simple; grows in meadows and elevated pastures with a calcareous soil, in England, as at Newmarket-heath, and Penny-bridge, Lancashire; perennial, and flowers in July.

Ver. *Serpyllifolia*, Thyme-leaved or Smooth Speedwell; with a terminal raceme, approaching to a spike; leaves ovate, slightly notched, smooth, and three-nerved; is common in meadows and pastures of Britain, and flowers in May and June.

Ver. *Becabunga*, Brooklime; with lateral racemes, plain, elliptical leaves, and creeping stem; is not uncommon in rivulets, and ditches with clear water; is perennial, and flowers in July.

Ver. *Anagallis*, Water Speedwell or Long-leaved Brooklime; with opposite lateral racemes, lanceolated serrated leaves, and upright stem; is not uncommon in ditches and marshes of this country; flowers in July; and is easily distinguished from the former by its lanceolate leaves and erect stem.

Ver. *Chamædrys*, Germander Speedwell, or Wild Germander; racemes lateral, leaves ovate, sessile, wrinkled, serrated, the stem hairy on two sides; very common in meadows and pastures, and under warm hedges; flowers in May and June, and is easily recognised by its beautiful blue flowers.

Ver. *Hederifolia*, Ivy-leaved Speedwell; with solitary flowers, heart-shaped, plain, five-lobed leaves, segments of the calyx heart-shaped, seeds pitcher-shaped; annual, and very common in gardens and fields; flowering from April to September.

Verbena, Vervain. *Gen. char.*—Cor. funnel-shaped, nearly equal; curved calyx with a single truncated tooth; seeds two or four, as the stamens are two or four, which happens in the species of this genus.

Ver. *Aubletia*, Rose-Vervain; with 4 stamens, loose solitary spikes, and trifid notched leaves; native of North America; is biennial; flowers in June and July; and the brilliancy of its scarlet flowers renders it a charming ornament of the greenhouse. Plate 31. Fig. 2.

Ver. *Triphylla*, Three-leaved Vervain; tetrandrous, flowers paniculated, leaves ternate, stem shrubby; native of South America, and common in the green-house, where it is easily recognised by the three leaves in a whorl, and the agreeable fragrance which every part of the bruised plant emits. *Bot. Mag.* II. 367.

Rosmarinus *Officinalis*, Common Rosemary. *Gen. char.*—Cor. unequal, upper lip two-parted, filaments long, curved, simple, with a tooth. *Spec. char.* Leaves sessile. Native of south of Europe, but common in gardens, where its large flowers afford an easy investigation.

Salvia. *Gen. char.*—Cor. unequal, filaments two, short, transversely attached to a small footstalk.

Sal. *Verbenacea*, Wild English Clary; leaves serrated, sinuated, and somewhat smooth; the corolla narrower than the calyx. In dry stony places in Britain; perennial; flowers from June to October.

Sal. *Horminum*, Purple-topped Clary; with blunt crenated leaves, and with bracteas at the top of the stem, coloured and larger. Native of Greece; but is well known as an annual in the flower-garden by its blue and purple tops, which are sometimes taken for flowers.

Order II. Digynia.

Anthoxanthum *Odoratum*, Sweet-scented Vernal Grass. *Gen. char.*—Cal. a glume with two valves including one flower; cor. a two-valved glume, awned. *Spec. char.* Spike ovate-oblong, the florets on little footstalks longer than the awn. This grass is very common in meadows and pastures, flowers in May, and communicates a fine fragrance to hay; and is a remarkable exception to the tribe of grasses which have three stamens, and are therefore arranged under the third class.

ORDER III. TRIGYNIA.

PIPER, *Gen. char.*—Cal. none; cor. none; berry roundish, containing one seed.

Pip. *Nigrum*, Black Pepper; leaves ovate, seven-nerved, smooth, foot-stalks simple. This plant, which is shrubby and creeping, is a native of the East Indies, and is extensively cultivated in Java and other places, on account of the berries which afford the black pepper of commerce, and are well known by their hot and aromatic taste as a spice or condiment. The berries are collected before they are ripe, and, being dried in the sun, become wrinkled and black, and are known under the name of black pepper; but when the fruit is fully ripe, and the external coat is separated by maceration in water, the berry exhibits a smooth surface, is less hot to the taste, and is the white pepper of commerce.

The species belonging to this genus are very numerous, and some of them are natives of Jamaica and the other islands in the West Indies, of South America, and of the South sea islands.

CLASS III. TRIANDRIA. Three Stamens.

This class is divided into three orders.

ORDER I. MONOGYNIA.

VALERIANA. *Gen. char.*—Cal. none; cor. monopetalous; gibbous at the base on one side, superior; one seed.

Val. *Dioica*, Small or Marsh Valerian; flowers triandrous, diœcious, (that is, the stamens on one plant and the pistils on another,) radical leaves ovate, stem leaves pinnated. Native of Britain; grows in wet and marshy meadows; is perennial, and flowers in June.

Val. *Officinalis*, Great Wild Valerian; flowers triandrous, leaves pinnated, leaflets lance-shaped, nearly uniform; a common plant on the banks of rivers and in marshy places; is perennial, and flowers in June. The roots of this plant are employed in medicine, and are well known for a peculiar odour which seems to be extremely grateful to some animals; cats are very fond of it, and it is said also that rats are attracted by the smell.

CROCUS. *Gen. char.*—Cor. six-parted, superior, tube very long, stigma convolute, eroded, spathe one-valved, radical.

Croc. *Sativus*, Saffron Crocus; with tripartite produced stigma, segments linear; flowers in September, and is extensively cultivated in Cambridgeshire, and about Saffron Walden in Essex, from which it has spread to the neighbouring fields, and grows in meadows and pastures. The summits of the pistils are collected and dried, and constitute the saffron of the shops.

Croc. *Vernus*, Spring or Garden Crocus; with trifid included stigma, and deeply cut wedge-shaped lobes; flowers in March, and is well known as one of the earliest ornaments of the parterre, where it appears with purple, white, and yellow flowers.

Croc. *Nudiflorus*, Naked Flowering Crocus; with trifid included stigma; is remarkable for the flower appearing in autumn without the leaves, from whence it is called autumnal and naked crocus.

IRIS. *Gen. char.*—Cor. six-parted, superior; the petals alternately reflected; stigmas petal-shaped.

Ir. *Pseudacorus*, Yellow Iris, or Water Flower-de-luce. Cor. without beards; interior petals less than the stigma; leaves sword-shaped; perennial; flowers in July, and is very common in wet ground.

Ir. *Fœtidissima*, Gladwin or Stinking Iris.—Cor. without beards, interior petals very spreading, stem one-angled, leaves sword-shaped; in shady woods and hedges; not uncommon in the west of England; perennial, flowers in June, and is easily recognized by its unpleasant odour.

Ir. *Persica*, Persian Iris; cor. unbearded, interior petals very short, spreading horizontally: A native of Persia, and a great favourite with the florist for its early appearance in February or March, and the beauty and fragrance of its flowers.

Ir. *Florentina*, Florentine Flag; cor. bearded, with pale green leaves shorter than the stem. Native of Italy and the south of Europe; grows abundantly on the walls of Florence, and is planted about graves in Algiers. The dried root furnishes the orris powder of commerce, which is extensively employed as a perfume. *Bot. Mag.* xviii. 671.

Ir. *Lurida*, Dingy Flag; bearded, with a stem nearly one-half longer than the leaves; native of the south of Europe, is cultivated in gardens, and flowers in May. *Bot. Mag.* xviii. 669. and Plate 31. Fig. 3.

Ir. *Susiana*, Chalcedonian Iris; with smooth, sword-shaped leaves, scape one-flowered, petals rounded; is a native of Persia, as the trivial name imports, and is the most magnificent of the Iris tribe; is cultivated in gardens, but is impatient of moisture, and flowers in June. *Bot. Mag.* iii. 91.

SCHOENUS. *Gen. char.*—Glumes chaffy, crowded, the exterior barren; cor. none; one seed, roundish.

Sch. *Mariscus*, Prickly or Long-rooted Bog-rush; with a round stem, and leaves acutely serrated on the margin and back; native of England, grows in marshes, and is very common on the moors near Cambridge.

Sch. *Albus*, White-headed Bog-rush; with a leafy triangular stem, flowers fasciculated, and bristly leaves; common in marshy places, particularly in Scotland; is perennial, and flowers in August.

Many species belonging to this genus are natives of tropical regions, particularly *restioides* and *cladium*, the former of which grows to the height of six feet, and the latter from eight to ten feet, in moist places and sea-marshes in Jamaica.

CYPERUS. *Gen. char.*—Glumes chaffy, imbricated on two sides; cor. none; one seed, without awn.

Cyp. *Longus*, Sweet Cyperus, or English Galingale; with a leafy triangular stem, a leafy divided umbel, naked peduncles, and alternate spikelets; perennial, and flowers in July; is a rare plant in England, but is met with in the isle of Purbeck, and near St David's Head.

Many species belong to this genus, chiefly natives of warm climates.

Cyp. *Elegans,* is a splendid species which grows in the sea-marshes near Lignanea in Jamaica. The root-leaves are from two to three feet in length, the stalk rises two feet and a half, with two or three leaves on the top, one of which is a foot long; and the elegant panicle is composed of numerous spikelets, some of which are sessile, and some are elevated on peduncles three or four inches long.

Cyp. *Odoratus,* Sweet-scented Cyperus, a native of low lands in the same island, exceeds five feet in height. Cyp. *Papyrus,* a native of Egypt, is still a loftier plant, which is alluded to by the ancients, and seems to have furnished the first materials for the manufacture of paper.

Scirpus. *Gen. char.*—Glume chaffy, imbricated on all sides; cor. none; one seed.

Scir. *Palustris,* Marsh-creeping Club-rush; with a round stem, sheathed at the base, spike terminal, nearly oval, glumes acute, root creeping; very common in ditches, marshes, and small streams; is perennial, and flowers in June and July.

Scir. *Lacustris,* Bull-rush; stem round, naked, panicle cymose, terminal, spikelets ovate; is common in clear water, as in still rivers and lakes; is perennial, flowers in July, and rises to the height of four or five feet.

The Bull-rush is also a native of Jamaica, where it is employed, as in England, in thatching cottages and stuffing chair-bottoms.

This is also a very numerous genus, the species of which are spread over the southern parts of Europe, the East and West Indies, and America.

Eriophorum, Cotton-grass. *Gen char.*—Glumes chaffy, imbricated on all sides; cor. none; seed one, surrounded with very long wool.

Er. *Vaginatum,* Single-headed Cotton-grass; with round sheathed stems, solitary spike, and membranous glumes; perennial, flowers early in the spring, and is common in marshy and boggy places throughout Britain.

Er. *Polystachion,* Broad-leaved Cotton-grass; with round stems, plain leaves, and spikes with foot-stalks; is perennial; flowers in April, and is equally common.

Er. *Angustifolium,* Common Cotton-grass; with round stems, grooved leaves, triangular at the top, and spikes on foot-stalks; grows in similar places with the preceding.

Nardus *Stricta,* Mat-grass. *Gen. char.*—Cal. none; cor. a two-valved glume. *Spec. char.*—Spike setaceous, upright, with the flowers on one side. Perennial; flowers in July, and is very common in moist sandy heaths. This grass is separated from its natural family by having only one pistil.

Order II. Digynia.

This order includes almost the whole of the valuable tribe of grasses, which either grow up spontaneously, or are cultivated for the sake of their leaves as food for domestic animals, or for the sake of their seeds as food for man. A few of the more common may be noticed.

Phleum. *Gen. char.*—Cal. two-valved, truncated acuminated, sessile, one flowered, including the corolla.

Ph. *Pratense,* Common Cats-tail Grass, or Timothy-grass; with a very long cylindrical spike, the glume ciliated on the back, longer than the awn; perennial; flowers from June to October, and is common in meadows and moist pastures. This grass sometimes rises to the height of three or four feet.

Alopecurus, Fox-tail Grass. *Gen. char.*—Cal. two-valved; one flowered; cor. one-valved.

Al. *Pratensis,* Meadow Fox-tail Grass; with a smooth erect stem, spike somewhat lobed; glumes of the calyx villous, and united at the base; perennial; flowers in May, and is very common in meadows and pastures.

Al. *Geniculatus,* Floating Fox-tail Grass; with an ascending kneed stem, spike slightly lobed and cylindrical, glumes hairy, retuse; perennial; flowers in July, and is common in pools and watery places.

Agrostis. *Gen char.*—Cal. two-valved, one-flowered, valves acute; cor. two-valved, unequal, larger than the calyx; stigmas plumose.

Ag. *Vulgaris,* Fine Bent-grass; with a spreading panicle, the little branches capillary, divaricated, calyces equal, the interior petal one-half shorter; perennial; flowers in July, and is common in meadows and pastures.

Ag. *Stolonifera,* Creeping Bent-grass; panicle compact, with a branchy creeping stem, florets crowded, calyces equal, downy; perennial; flowers in July and August, and is common in moist meadows. This is the celebrated fiorin-grass, which has been most injudiciously and erroneously recommended for all soils and situations.

Ag. *Alba,* Marsh, or Wood Bent-grass; with a loose panicle and creeping stem; perennial; flowers in July, and grows in ditches and marshy places. This species has been also cultivated as fiorin grass.

Poa. *Gen. char.*—Cal. two-valved, many flowered, spikelets rounded at the base; cor. two-valved, ovate, valves somewhat acute.

Poa *Trivialis,* Roughish Meadow-grass; panicle diffuse, spikelets three-flowered, glumes lance-shaped, five-nerved, straw upright and rough; perennial; flowers through the summer, and very common in meadows and pastures.

Poa *Annua,* Annual Meadow-grass; panicle divaricated, spikelets ovate, and chiefly four-flowered, with an oblique compressed stem; flowers through the whole summer, and is one of the most common grasses.

Stipa *Pennata,* Feather-grass. *Gen. char.*—Cal. two-valved, one flowered; cor. exterior valve, with a very long terminal awn, articulated at the base. *Spec. char.*—Awns woolly; perennial; flowers in July; and is cultivated in the garden on account of its beautiful awns.

Avena. *Gen. char.*—Cal. two-valved, many flowered; cor. exterior valve awned on the back, awn twisted.

Av. *Fatua,* Wild-oat, or Haver; paniculated, calyx containing about three flowers, the florets hairy at the base, and all of them awned, and without nerves;

annual; flowers in August, and is not uncommon in fields and among corn.

To this genus belong the numerous varieties of the cultivated oat, beside many other species, some of which are native and some are exotic.

Arundo *Phragmites*, Common Reed. *Gen. char.* Cal. two-valved, florets surrounded with persistent down. *Spec. char.*—Cal. five-flowered, panicle lax. Perennial; flowers in July, and is well known as a native of ditches, stagnant waters, and banks of rivers.

Saccharum *Officinarum*, Sugar-cane. *Gen. char.* Cal. two-valved, covered with down at the base, one-flowered; cor. two-valved. *Spec. char.*—Flowers panicled, and flat leaves. This valuable vegetable is a native of India, South America, and the South-sea Islands; was introduced into Europe, it is supposed, during the crusades in the 12th century; and was planted in Spain, Madeira, the Canary, and Cape de Verd Islands, soon after their discovery in the 15th century; and from some of these islands found its way to the West Indies, where it is now so extensively cultivated. Several varieties of this plant are known; and, in the year 1796, a new variety, called the Bourbon, or Otaheite cane, of a larger size, and more productive, was introduced into Jamaica.

A rich, deep, and open soil, is the most suitable for the culture of the sugar-cane. Trenches, six or eight inches deep, and at the distance of three feet and a half, are formed; and the cuttings of the canes, having five or six joints, are placed horizontally at the bottom of the trench, and covered with mould to the depth of two inches. The sprouts appear in twelve or fourteen days; and as they shoot up the soil is gradually drawn about them, till, in the course of a few months, the ridges of earth are all level.

The cane-plant, including its leaves and flower stem, rises to the height of twelve or fourteen feet; and when it arrives at maturity, which requires the period of a year or fourteen months, the canes are cut down, and the leaves and top being separated, the solid stems are tied up in bundles and carried to the mill, where they are passed through iron-plated rollers, and the juice is received in a proper vessel, from which it is conveyed to boilers, where it is boiled down and concentrated; a quantity of quicklime is added, to separate some acid, which would prevent the crystallization, and some blood, or similar animal matter, is mixed with it, for the purpose of clarifying the liquid. When it is sufficiently concentrated and purified, the syrup is conveyed to coolers, where the sugar crystallizes, and the molasses separate. The sugar is then carried to the hogsheads in the curing-house, the bottoms of which are perforated that the molasses may drain off into a cistern below; and when the sugar is sufficiently dry it is brought to market under the name of *muscovado*, or *raw sugar*.

To this order also belong those plants which come under the denomination of *cerealia*, or those which produce corn, such as wheat, barley, rye, and oats; one species of which has been already mentioned.

Order III. Trigynia.

Montia *Fontana*, Water Chickweed.—*Gen. char.* Cal. two-leaved; cor. monopetalous, irregular; caps. one-celled, three-valved, three-seeded. This is the only species. It is annual; flowers in April and May, and is not uncommon near springs and moist places.

Holosteum. *Gen. char.*—Cal. five-leaved; petals five eroded; caps. 1-celled, nearly cylindrical, opening at the top.

Hol. *Umbellatum*, Umbelliferous Chickweed; with umbellated flowers. Is annual; flowers in April, and is sometimes met with on old walls, as the walls of Norwich. Several other species are natives of tropical regions.

Class IV. Tetrandria,

With four stamens and three orders.

Order I. Monogynia.

Dipsacus. *Gen. char.*—Common calyx many-leaved, foliaceous; proper calyx superior, one-leaved, down cup-formed.

Dip. *Fullonum*, Cultivated or Fuller's Teasel; leaves connate, or united at the base, the chaff bent back, involucrum reflexed. This fine plant, which grows to the height of five feet, is biennial; flowers in July, and is cultivated on account of its heads, which are employed in the woollen manufactures to raise the nap of cloth.

Dip. *Sylvestris*, Wild Teasel; leaves opposite, serrated, chaff straight, involucrum bent inwards, and longer than the head; a smaller plant than the preceding; biennial; flowers in July, and grows in moist hedges and way-sides in England.

Scabiosa. *Gen. char.*—Common cal. many-leaved; proper, superior, double; receptacle chaffy, or naked.

Scab. *Succisa*, Devils-bit Scabious; florets quadrifid, equal; stem-leaves toothed, flowers nearly globular. Perennial; flowers in August, and is common in pastures. The trivial name is derived from the truncated or bitten appearance of the root.

Scab. *Arvensis*, Field-scabious; small corollas four-cleft, radiating; leaves pinnatifid, deeply cut, stem hairy. Perennial; flowers in July; is common in fields and meadows, and is easily distinguished from the preceding, particularly by its long branches and spindle-shaped root. The flowers exposed to the fumes of tobacco assume a bright green colour. *Smith.*

Sherardia *Arvensis*; Little-field Madder. *Gen. char.*—Cor. monopetalous, funnel-shaped, superior; seeds two, three-toothed. *Spec. char.*—Leaves whorled, flowers terminal. This beautiful little plant is annual, flowers through the whole summer, and is not uncommon among corn and in uncultivated fields.

Asperula *Odorata*, Sweet Woodroof. *Gen. char.* Cor. one-petaled, funnel-shaped, superior; seeds two, round. *Spec. char.*—Eight lanceolated leaves in the whorl, fascicles of flowers on footstalks. Perennial; flowers in May, is common in shady woods, and is collected on account of its fragrance. When dried it gives out the odour of benzoin.

Galium. *Gen. char.*—Cor. one-petaled, plain, superior; seeds two, roundish.

Gal. *Verum*, Yellow Bed-Straw, or Cheese-Rennet; with eight leaves, linear, furrowed, entire, rough; flowers paniculated and crowded; perennial; flowers in July and August, and is very common on dry banks. It is easily known by its bright yellow flowers, which emit the smell of honey.

Gal. *Aparine*, Goose-grass, or Cleavers; with eight leaves, lanceolate, keeled, rough, reversely prickled; stem flaccid, seeds rough. An annual plant; flowers in May and August, and is very common in hedges, on which its weak trailing stems are supported.

Plantago. *Gen. char.*—Calyx four-cleft; cor. four-cleft, inferior, limb reflected, stamens very long, capsule two-celled, opening horizontally.

Plan. *Major*, Greater Plantain; with ovate smoothish leaves, shorter than the footstalk, scape or flower-stem round, spike imbricated with flowers, seeds very numerous; perennial; flowers through the summer, and is one of the most common plants in meadows, pastures, and by way-sides.

Plan. *Media*, Hoary Plantain; with ovate downy leaves, longer than the footstalk. Is perennial; flowers through the summer, but is less common than the other species, from which it is readily distinguished by its dense spike and purple stamens, furnished with white anthers. Roman camp, near Dalkeith in Scotland, and on the walls of Carlisle castle.

Plan. *Lanceolata*, Ribwort Plantain; with lanceolate leaves and angular flower-stem. Is perennial; flowers in June and July, and is very common in meadows and pastures. Two other species, Plan. *Maritima*, Sea Plantain, with linear leaves, on the sea-shores; and Plan. *Coronopus*, Buckshorn Plantain, with pinnatifid leaves, in dry sandy places near the shore,—are natives of Britain.

Alchemilla. *Gen. char.*—Cal. eight-cleft, with the alternate segments smaller, inferior; cor. none; one naked seed.

Al. *Vulgaris*, Common Lady's Mantle; with leaves folded, lobed; perennial; flowers in June and July, and is very common in meadows and elevated pastures.

Al. *Alpina*, Alpine Lady's Mantle; with leaves digitate, serrated, covered underneath with a white silky down; perennial; flowers in July, and is a native of the mountains of Scotland and the north of England.

Protea. *Gen. char.*—Four-petaled, the petals uniting in different ways; the anther inserted on the petal below the apex; one seed, superior, naked.

Prot. *Cynaroides*, Artichoke-flowered Protea, or Silver-tree; with roundish, smooth leaves, on footstalks. This plant is a native of the Cape, is a low shrub remarkable for the magnificence of its flowers, and is cultivated in green-houses in the vicinity of London. *Bot. Mag.* 770.

Prot. *Cordifolia*, Heart-leaved Protea; with heart-shaped leaves, is a dwarf species, but is remarkable for the bright red colour of the stalks, and the red cartilaginous margin of the leaves. *Bot. Mag.* 649.

Prot. *Lepidocarpon*, Black-flowered Protea; with solitary flowers; rays of the calyx strap-shaped; incurvated, and bearded; leaves lanceolate; is also a native of the Cape of Good Hope, and has been admitted into the green-houses of this country. *Bot. Mag.* 674.

The structure of the flowers in the genus Protea is extremely curious. A great number of florets is inclosed within a common calyx, which is formed of many imbricated leaves or scales, and all attached to a common receptacle; and some parts of the flower are covered with fine hairs or down, from which the name of Silver-tree is derived.

Banksia *Ericifolia*, Heath-leaved Banksia. *Gen. char.*—Amentum or catkin scaly; cor. four-petaled; anthers sessile, in a cavity of the segments; caps. two-valved; two-seeded. *Spec. char.*—Leaves approximate, acerose, smooth. Native of New Holland, but is an inmate of the greenhouse of this country. The generic name is intended to commemorate the first discovery of the plant by Sir Joseph Banks. Several other species have been added, and all natives of the same region. The length and undulating appearance of the style adds greatly to the beauty of the flower; and the stigma being retained within the corolla till the petals are fully expanded, exhibits the singular appearance of each flower being furnished with a loop. *Bot. Mag.* 738. See Plate 31. Fig. 4.

Order II. Digynia.

Buffonia *Tenuifolia*, Slender Buffonia. *Gen. char.*—Cal. four-leaved; cor. four-petaled; caps. one-celled; double seeded. An annual plant; flowers in June; but is rare in this country.

Order III. Tetragynia.

Ilex. *Gen. char.*—Cal. four or five-toothed; cor. wheel-shaped; no styles; some flowers are four-cleft, and have only stamens.

Il. *Aquifolium*, Holly-tree; with ovate, acute, spinous leaves; flowering in May, and common in hedges and woods. The holly is well known by its beautiful evergreen leaves and scarlet berries, which stand through the winter. The wood, which is susceptible of a fine polish, is employed by the cabinet-maker, and common birdlime is prepared from the bark.

Potamogeton. *Gen. char.*—Cal. none; petals four; no style; four seeds.

Pot. *Natans*, Broad-leaved Pondweed; with the upper leaves longish, ovate; foot-stalked; floating. Perennial; flowers in July, and is common in rivers and stagnant waters.

Pot. *Lucens*, Shining Pondweed; with ovate, lanceolate, plain leaves, diminishing into footstalks; perennial; flowers in June and July, and is frequent in ditches, rivers, and lakes. The flower-spike only of this plant appears above water.

Pot. *Pectinatum*, Fennel-leaved Pondweed; with setaceous, parallel, approaching leaves, set on two sides of the stem, and sheathing at the base; perennial; flowers in July, and not uncommon in rivers and pools, and is also met with in salt-water ditches.

Sagina. *Gen. char.*—Cal. four-leaved; petals four; caps. one-celled.

Sag. *Procumbens*, Procumbent Pearlwort; with procumbent, smooth stems, and very short petals; perennial; flowers from May to August, and is a common plant in sandy places, on walls, and in the neglected walks of gardens.

Sag. *Apetala*, Annual small-flowered Pearl-wort; with downy, somewhat erect stalks, and obsolete petals; annual; flowers in May and June, and is common on walls and sandy places.

Class V. Pentandria. Five Stamens.

This is a very large class, and is divided into six orders.

Order I. Monogynia. One Style.

Heliotropium. *Gen. char.*—Cor. salver-shaped, five-cleft, with teeth between; seeds four; throat closed with arches.

Hel. *Peruvianum*, Peruvian Turnsole; with lanceolate, ovate leaves, shrubby stem, and numerous aggregated corymbose spikes; native of Peru, as the name indicates, but seldom absent from the greenhouse or stove, on account of the delicious fragrance of its flowers.

Echium. *Gen. char.*—Cor. with a naked throat, irregular; stigma two-parted.

Ech. *Vulgare*, Common Viper's Bugloss; with a hairy, tuberculated stem; stem-leaves hairy, lanceolate; spikes lateral, deflected. Biennial; flowers in June and July, and is common in fields and waste places.

Ech. *Italicum*, White Viper's Bugloss; in which the stamens are very long. Is common on sandy grounds in the island of Jersey.

Lycopsis. *Gen. char.*—Cor. tube incurvated, closed with convex scales.

Lyc. *Arvensis*, Small Bugloss; with rough, lanceolate leaves; annual; flowers in June and July, and is very common in fields and by waysides, where it is easily recognised by its beautiful blue flowers, and the curved tube of the corolla.

Symphytum. *Gen. char.*—Cor. limb tubulated, ventricose; throat closed with awl-shaped rays; cal. five-parted.

Sym. *Officinale*, Comfrey; with leaves ovate, lanceolate, decurrent; perennial; flowers in May and June, and is not uncommon in moist and shady places.

Sym. *Asperrimum*, Prickly Comfrey; with prickly stalks; acute, ovate leaves on footstalks; floral leaves opposite; racemes double. This splendid species is a native of Caucasus, is a hardy perennial, rises to the height of five feet, and with its blue and red flowers is a fine ornament of the shrubbery. *Bot. Mag.* 927.

Borago. *Gen. char.*—Cor. wheel-shaped, throat closed with rays.

Bor. *Officinalis*, Common Borage; with all the leaves alternate; biennial; flowers in June and July, is a common plant in the garden, and is sometimes met with in waste places, and by way-sides.

Pulmonaria. *Gen. char.*—Cor. funnel-shaped, with an open throat; cal. prismatic, five-angled.

Pul. *Officinalis*, Common Lungwort; cal. of the same length as the tube; leaves ovate, rough; perennial; flowers in May, is common in gardens, and sometimes appears in woody places.

Pul. *Maritima*, Sea Bugloss, or Lungwort; cal. shortened; leaves ovate, azure-coloured; stem branching, procumbent. Perennial; flowers in July, and with its beautiful blue and red flowers, contrasted with elegant waved azure leaves, adorns the sandy shores of the western coasts of Scotland and north of England.

Myosotis *Scorpioides*, Mouse-ear Scorpion Grass. *Gen. char.*—Cor. salver-shaped, five-cleft, slightly notched, throat closed with arches.—*Spec. char.* Seeds naked, leaves elliptical-lanceolate; racemes many flowered, without bracteas. A very common plant, and greatly diversified in its habits and appearance, from soil and situation. In dry shady places it is rough and hairy, but on a wet soil it is quite smooth. Its beautiful blue flowers, which are of a fine flesh colour before expansion, cannot fail to excite admiration.

The plants now described, from the roughness of the leaves, belong to the natural order *asperifoliæ*, or rough-leaved plants; and on examination it will be found that a general uniformity of character in other respects prevails, and particularly in the evolution of the flower stem.

Primula. *Gen. char.*—Cap. one-celled, mouth ten-cleft; tube of the corolla cylindrical, stigma round.

Prim. *Vulgaris*, Common Primrose; with leaves toothed, wrinkled; scape or flower-stem one-flowered, limb of the corolla plain; perennial; is the well known harbinger of spring, and is very common in woods and hedges.

Prim. *Elatior*, Oxlip, or great Cowslip; with toothed and wrinkled leaves contracted in the middle, many flowered scape, limb of the corolla plain; perennial; flowers in April, and grows in pastures and among brushwood, but is not very common.

Prim. *Veris*, Common Cowslip, or Paigle; differs from the preceding by the limb of the corolla being concave; is also perennial; and is common in meadows and pastures in England.

Prim. *Farinosa*, Birds-eye Primrose; with smooth crenated leaves, dusty underneath; is also perennial; flowers in June and July, and with its elegant flowers adorns the mountainous pastures in the north of England, and grows plentifully in a meadow north from Stromness in Orkney.

All the varieties of polyanthus which have arisen from long and repeated culture, derive their origin from the species of primula now described; and from another species, *Primula Auricula*, all the beautiful varieties of the auricula which adorn the flower garden in the spring, have proceeded.

Soldanella *Alpina*, Alpine Soldanella. *Gen.*

Pentandria.

char.—Cor. bell-shaped, deeply divided, or fringed; caps. one-celled. Of this genus this beautiful species only is known; it is a native of the elevated regions of Switzerland and Germany; grows readily in this country, and expands its fine blue or white blossoms in March.

Dodecatheon *Meadia*, American Cowslip; is a native of Virginia, common in gardens, and is easily recognised by its wheel-shaped corolla, the segments of which are bent back.

Menyanthes. *Gen. char.*—Cor. villous; stigma bifid; caps. one-celled.

Men. *Trifoliata*, Marsh Trefoil, Buck-bean, or Bog-bean; with ternate leaves, upper surface of the corolla villous; perennial; flowers in June and July, and is very common in marshy places. The elegant flowers of this plant, which are of a pure white, or delicately tinged with pink, and beautifully fringed on the upper surface, will amply reward a minute examination.

Anagallis. *Gen. char.*—Cor. wheel-shaped, caps. divides horizontally, stamens furnished with jointed hairs.

An. *Arvensis*, Scarlet Pimpernel; leaves ovate, dotted on the lower surface; stem procumbent. Annual; flowers in June and July, and is common in corn fields and gardens. This beautiful little plant, varieties of which appear with blue and white flowers, will recommend itself to the attention of the botanist by the curious jointed structure of the hairs on the filaments, which may be seen by a hand magnifier, but more distinctly with a microscope of greater power, and also by its seed-vessel, which divides into hemispheres.

An. *Monelli*, with fine blue flowers; a native of Spain and Italy, has been long an inmate of the green-house; and *Fruticosa*, Shrubby Pimpernel, with large orange flowers, supposed to be a native of Africa, has been lately introduced.

Azalea. *Gen. char.*—Cor. bell-shaped, stamens attached to the receptacle, caps. five-celled.

Az. *Procumbens*, Trailing Azalea; with diffuse procumbent branches, and opposite, very smooth revolute leaves; is a native of the high mountains of Scotland.

Az. *Pontica*, Yellow Azalea; with lance-shaped, shining leaves; is a native of mount Caucasus, and the banks of the Dnieper, and is now cultivated in gardens; rises to the height of two or three feet, and produces umbels of fragrant flowers at the extremities of the branches.

Convolvulus. *Gen. char.*—Cor. bell-shaped, folded; stigmas two; caps. two or three-celled, with two seeds in each.

Con. *Arvensis*, Small Bindweed; with arrow-shaped leaves, acute on both sides; one-flowered peduncles, and minute bracteas remote from the flower. Perennial; flowers in June and July, and is a very common weed in fields and gardens.

Con. *Sepium*, Great Bindweed; with arrow-shaped leaves, and one-flowered angular peduncles; is perennial; grows in moist hedges, where it is readily distinguished by its large white or pinkish flowers.

Con. *Soldanella*, Sea Bindweed, with kidney-shaped leaves, and one-flowered peduncles; perennial; flowers in July, and is a native of particular spots on the sandy shores of the western parts of Scotland. Its specious reddish flowers are highly ornamental to the barren shores.

Pentandria.

Polemonium *Cæruleum*, Jacob's Ladder, or Greek Valerian. *Gen. char.*—Cor. five-parted, stamens inserted on scales shutting the base of the corolla; stigma three-cleft; caps. superior, three-celled. *Spec. char.*—Leaves pinnated, flowers erect, with the calyx longer than the tube of the corolla. This plant offers itself for examination in every garden, and varies with blue and white flowers.

Campanula. *Gen. char.*—Cor. bell-shaped, the bottom closed with valves supporting the stamens; stigma three-cleft; caps. inferior, opening by lateral pores.

Cam. *Rotundifolia*, Round-leaved Bell-flower; with radical leaves kidney-shaped, stem leaves linear; perennial; flowers in August and September, and is very common on heaths, walls, and about the borders of fields.

Cam. *Latifolia*, Giant Bell-flower; with ovate lanceolate leaves, very simple round stem, and one-flowered peduncles; perennial; flowers in August, and is not uncommon in woods and shady places, both on the east and west of Scotland.

Cam. *Speculum*, Venus' Looking-glass; with branched diffuse stem, oblong slightly crenated leaves, and solitary flowers; is a native of the south of Europe, and generally finds a place among the ornamental annuals of the garden, to which the brilliancy of its flowers justly recommends it.

Cinchona. *Gen. char.*—Cor. shaggy, stigma simple; caps. two-celled, opening within; seeds numerous.

Cin. *Officinalis*, and some other species of the same genus, which grow to the size of trees, furnish the pale, yellow, and red bark, which are so extensively employed in medicine. From the place of their growth it is called Peruvian Bark; and the generic name, *Cinchona*, is said to have been derived from the Countess del Cinchon, the lady of a Spanish viceroy, who was cured by its use about the year 1640; and being recommended by the Jesuits, it obtained the designation of Jesuits bark.

Cin. *Caribbea*, called in Jamaica, *Sea-side Beech*, is a tree which rises to the height of fifteen or twenty feet, and was brought into notice by Dr Wright, who found that it was not less efficacious in the cure of fevers than the Peruvian bark. Two other species have been discovered in Jamaica.

Coffea. *Gen. char*—Cor. salver-shaped, five-cleft; stigma two-parted; berry two-seeded.

Several species of this genus have been described. *Occidentalis* is a native of the West Indies; but *Coffea Arabica* or Coffee-tree, originally from Arabia as the name imports, is the cultivated species. The leaves are opposite, and many sessile flowers are produced at their insertion. The coffee tree naturally rises to the height of 17 or 18 feet; but when under culture it is kept at five or six feet, for the convenience of collecting the ripe berries. The trees are planted

Pentandria.

in regular rows; and when they are in full bloom nothing can exceed the beauty of their pure, white, clustered flowers, and the delicious perfume which they exhale; the air is filled with fragrance, and the trees seem as if covered with a shower of snow, affording a fine contrast to the dark green foliage. But this enchanting scene is of transient duration; the flowers decay a few hours after they are full blown, and all the beauty and fragrance which delighted the senses in the morning, have vanished before noon. The berries which succeed the flowers are first green, when fully grown become red, ripen into a dark purple, and at last shrivel and drop from the tree. The fruit is fit for collecting about seven months from the appearance of the flowers. The berries are either dried on platforms, or the pulp is bruised by means of a machine, or passed through the grating-mill, by which the pulp is torn off, and the seeds completely separated; they are then washed in water, dried in the sun or by means of artificial heat, and afterwards put up in bags for the market.

Viola. *Gen. char.*—Cor. five-petaled, irregular, horned behind; anthers united; caps. superior, three-valved, one-celled; cal. five-leaved, lengthened at the base.

V. *Odorata*, Sweet Violet; without stem, shoots creeping, leaves heart-shaped, with smoothish footstalks; perennial; flowers in March and April, and grows in woods and hedges. Cultivated in the garden for the sake of its fragrant flowers.

V. *Tricolor*, Pansy Violet, Heart's Ease; stem angular, leaves oblong, toothed, crenated, with lyre-shaped pinnatifid stipulæ; annual; flowers through the summer.

V. *Lutea*, Yellow Mountain Pansy; with triangular stem, and leaves ovate-oblong, crenated and ciliated; perennial; flowers through the summer, and is common in mountainous pastures in Scotland and the north of England.

Hyoscyamus *Niger*, Common Henbane. *Gen. char.*—Cor. funnel-shaped, obtuse, irregular; stamens inclined; caps. covered, two-celled. *Spec. char.* Leaves embracing the stem; flowers sessile. Annual; flowers in July, and is frequent in waste places about towns and villages. The calyx is finely reticulated, and the yellow corolla is beautifully marked with purple veins; but the whole plant is of a poisonous and narcotic quality.

Atropa *Belladonna*, Deadly Nightshade. *Gen. char.*—Cor. bell-shaped; stamens distant; berry superior, two-celled. *Spec. char.*—Stem herbaceous; leaves ovate, entire. Perennial; flowers in June, and grows in waste places, but rarely. We have only met with this plant, in Scotland, near the ruins of religious houses,—at Lincluden near Dumfries, and Kinloss Abbey in Morayshire, which has excited a conjecture that it may have been originally introduced. The berries are a deadly poison.

Solanum. *Gen. char.*—Cor. wheel-shaped; anthers slightly united, opening at the top by a double pore; berry superior, two-celled.

Sol. *Dulcamara*, Woody Nightshade, or Bitter-Sweet; with a shrubby, waving, unarmed stem, upper leaves halberd-shaped, racemes cymose; a shrubby plant; flowers in June and July; and is common in moist hedges, where it is conspicuous by its climbing stalks, purple flowers, and red berries.

Pentandria.

Sol. *Nigrum*, Common or Garden Nightshade; with herbaceous unarmed stem, and nodding lateral umbels; flowers through the summer, produces black berries, and grows in waste places. Both species are poisonous.

To this genus belongs the common potatoe, Solanum *Tuberosum*, the varieties of which, from culture and diversity of soil and situation, are almost endless. Its large flowers afford great facilities in examining the characters of the genus.

Lonicera. *Gen. char.*—Cor. monopetalous, irregular; berry many-seeded.

Lon. *Caprifolium*, Pale Perfoliate Honeysuckle; with flowers ringent, whorled, terminal; deciduous leaves; upper leaves perfoliate; shrubby; flowers in May and June, and grows in woody places.

Lon. *Periclymenum*, Common Honeysuckle, or Woodbine; with flowers in ovate, imbricated, terminal heads; all the leaves distinct and deciduous; shrubby; flowers in June and July, and is common in woods and hedges.

Ribes. *Gen. char.*—Cal. superior, bell-shaped, five-cleft; petals and stamens inserted in the calyx; style two-cleft; berry many-seeded.

Rib. *Rubrum*, Common Currants; unarmed; with smooth pendulous racemes; plain flowers; petals obcordate; flowers in May, and is a native of woods and banks of rivers in the north of England, and of the island of Isla in Scotland, but is well known as the red and white currants of the garden.

Rib. *Nigrum*, Black Currants; with racemes hairy, pendulous, and with a simple peduncle at the base; grows wild in some parts of England and in Isla, but, from being universally cultivated, is equally familiar.

Rib. *Grossularia*, Rough Gooseberry; with prickly branches; footstalks of the leaves hairy; peduncles one-flowered; fruit rough.

Rib. *Uva-Crispa*, Smooth Gooseberry; is reckoned a distinct species, but is scarcely different, except in the smoothness of the fruit. From these two species all the varieties of the gooseberry have been produced.

Hedera *Helix*, Common Ivy. *Gen. char.*—Cal. five-toothed; petals five, dilated at the base; berry five-seeded, surrounded by the calyx. *Spec. char.* Leaves ovate-lobed. This well known plant flowers in October, and affords a fine example of the *caulis radicans*, or rooting stem, which throws out fibres for its support, and attaches itself to walls or trees, as it creeps along. The leaves on the stem are five-lobed, but on the top of the branches they are ovate and undivided.

Order II. Digynia. With two Styles.

Ulmus. *Gen. char.*—Cal. five-cleft, inferior, permanent; cor. none; caps. membranaceous, compressed, one-seeded.

Ulm. *Campestris*, Common Elm; with leaves doubly serrated, rough, and unequal at the base; the flowers appear in April, and it is easily distinguished by the inequality of the leaves.

Ulm. *Montana*, Broad-leaved Elm, or Witch Hazel; is distinguished from the preceding by its broader, less rough, pointed leaves; flowers at the same time, and is common in woods and hedges.

Gentiana. *Gen. char.*—Cor. tubular at the base; destitute of nectariferous pores; caps. superior, one-celled, two-valved, many-seeded.

Gen. *Verna*, Spring Gentian; with five-cleft, salver-shaped, crenated corolla; segments with appendages at the base; leaves ovate, crowded together. Perennial; flowers in April, and is a native of the mountains in the north of England and in Ireland; but is an early and beautiful ornament of the garden.

Gen. *Campestris*, Field Gentian; with four-cleft, salver-shaped corolla; bearded at the throat; interior segments of the calyx very large. Annual; flowers in September; and grows in dry upland pastures, and in sandy downs near the sea.

Stapelia. *Gen. char.*—Cor. wheel-shaped, with a double star-like nectary covering the parts of fructification.

Stap. *Grandiflora*, Great Flowered Stapelia; with club-shaped, quadrangular branches; the angles toothed; the corolla large, five-cleft; segments lanceolate, acute, and ciliated on the margin. *Bot. Mag.* 585. See Plate 31. Fig. 6.

All the species of this singular tribe of plants are natives of the arid deserts in the vicinity of the Cape of Good Hope. They are remarkable for the succulence of their stems and branches, which enables them to exist in a parched soil. The Stapelia, from a mistaken analogy, has been denominated the camel of vegetables, because it retains a large portion of fluid in the midst of those burning sands, where scarcely any other plants appear; but the resemblance between the animal and the vegetable does not hold with regard to structure, although the stapelia, in some of its properties, approaches to the nature of animal matter. Stap. *asterias*, star-fish stapelia, exhales the odour of putrid fish; and insects, attracted by the smell, deposit their eggs in some of the species as on animal matter.

Umbellated Plants.

In their general habits and appearance these plants exhibit a striking resemblance, and are therefore associated in the same natural order. They are subdivided into three sections, as they are furnished with an involucrum or are destitute of that appendage.

A. With universal and partial involucrum.

Eryngium. *Gen. char.*—Involucrum many-leaved, flowers in heads; common receptacle, conical, chaffy.

Eryn. *Maritimum*, Sea-holly; with radical leaves, roundish, folded, and spinous flower-heads, with foot-stalks; perennial; flowers in July and August, and is common on sandy shores.

Eryn. *Campestre;* with leaves embracing the stem, somewhat pinnated, and deeply cut; is also perennial; flowers in July and August, and is found, but more rarely, in pastures near the sea.

Conium *Maculatum*, Common Hemlock. *Gen. char.*—The small involucrum extending half round, and about three-leaved; fruit ovate, with five ribs on each side; petals equal. *Spec. char.*—With seeds smooth and much branched, stem shining, spotted. Biennial; flowers in June and July, and is one of the most common plants among rubbish and in waste places.

Heracleum *Sphondylium*, Common Cow-parsnep. *Gen. char.*—Fruit elliptical, compressed, striated, dilated with a margin; flowers radiating; petals inflected, emarginate; involucrum not permanent. *Spec. char.*—Leaves pinnated, the leaflets pinnatifid, cut, and serrated. Biennial; flowers in July, and is very common in hedges, on the borders of fields, and in moist meadows, where it is readily recognized by its tall stem, which rises to the height of four feet, and large leaves.

Daucus *Carota*, Wild Carrot. *Gen. char.*—Involucrum pinnatifid, flowers nearly radiated, fruit muricated. *Spec. char.*—Seeds rough, foot stalks of the leaves nerved beneath. Biennial; flowers in June and July, and is common everywhere in pastures and on the borders of fields.

B. With partial involucrum, none universal.

Cicuta *Virosa*, Water Hemlock. *Gen. char.*—Fruit nearly ovate, furrowed; cor. regular. *Spec. char.* Umbels opposite to the leaves, with obtuse stipulæ attached to the foot-stalk. Perennial; flowers in August, and grows in ditches and on the banks of rivers; but as it is a very poisonous plant, it is fortunately not common. It grows sparingly at the edge of Lochend lake near Edinburgh, and on the borders of one of the lakes at Lochmaben in the south of Scotland.

Æthusa *Cynapium*, Fools Parsley, or Lesser Hemlock. *Gen. char.*—Fruit striated, small involucrum, three-leaved, pendulous. This species is easily distinguished by its round, slightly striated stem, and smooth, deep green, doublypinnated leaves. Annual; flowers in July and August, and is a common weed in gardens. It has been sometimes mistaken for parsley, to which it has some resemblance; but as it is of a noxious quality, it should be carefully avoided.

Scandix. *Gen. char.*—Flowers radiating, petals emarginate, seed awl-shaped, flowers of the disk often with stamens only.

Scan. *Odorata*, Sweet Cicely, Great Chervil, or Myrrh; with angular furrowed seeds; flowers in May, and is common in waste places, but is always near houses; supposed not to be indigenous.

Scan. *Pecten-Veneris*, Venus's Comb, or Shepherd's Needle; with seeds furnished with very long beaks; common in cultivated fields; annual; and flowers in June and July.

C. With no involucrum.

Pastinaca *Sativa*, Wild Parsnep. *Gen. char.*—Seed elliptical, compressed-plain; petals rolled inwards, entire. *Spec. char.*—Leaves simply pinnated, hoary on the lower surface. Biennial, and rises to the height of three feet; flowers in July, and not uncommon on the borders of fields.

Apium *Graveolens,* Smallage, or Wild Celery. *Gen.char.*—Seed ovate, ribbed; petals inflected, equal. *Spec. char.*—Leaflets of the stem wedge-shaped, stem furrowed. Biennial, and flowers in August; in ditches and marshes near the sea; is acrid and poisonous, but becomes esculent when cultivated.

Ægopodium *Podagraria,* Gout-weed. *Gen. char.* Seed ovate-oblong, ribbed; petals inflected, heart-shaped, unequal. A troublesome weed in cultivated grounds and waste shady places. Perennial, and flowers in May and June.

Order III. Trigynia.

Sambucus. *Gen. char.*—Cal. superior, five-parted; cor. five-cleft, berry three-seeded.

Sam. *Ebulus,* Dwarf Elder; with three-parted cymes, and herbaceous stem; perennial; flowers in July, and grows in waste places and hedges, but not very common. The stem, which rises to the height of three feet, dies away in the winter.

Sam. *Nigra,* Common Elder; with five-parted cymes and arborescent stem; flowers in June, and is very common in hedges and woods, where it is easily recognized by its white fragrant flowers, and dark purple or white berries.

Order IV. Tetragynia.

Parnassia *Palustris,* Grass of Parnassus. *Gen. char.*—Cal. five-parted, petals five; nectaries five, heart-shaped, ciliated with globular summits; caps. four-valved; perennial; flowers in September and October, and is frequent in marshy soils, where it is easily distinguished by its angular twisted stem, bearing one leaf and one beautiful snow-white terminal flower; but the curious and elegant structure of the nectaries will not fail to excite the attention and admiration of the botanist.

Order V. Pentagynia.

Statice. *Gen. char.*—Cal. one-leafed, entire, folded, withered; petals five; seed one, superior.

Stat. *Armeria,* Thrift, or Sea-gilliflower; with simple stem, flowers capitate, leaves linear; perennial; flowers in July and August, and is common on slimy shores, and in moist alpine regions.

Stat. *Limonium,* Sea-Lavender, with a round paniculated stem; perennial; flowers in July and August, and grows also on muddy shores, but is less common.

Linum. *Gen. char.*—Cal. five-leaved; petals five; caps. superior, ten-valved, ten-celled, seeds solitary.

Lin. *Usitatissimum,* Common Flax; with the leaves of the calyx ovate, acute, three-nerved, petals crenated, leaves lanceolate alternate; annual; flowers in July, and sometimes appears among corn, but is well known as the cultivated species of flax.

Lin. *Catharticum,* Purging Flax; with leaves opposite, stem divided above; petals acute; annual; flowers from June to August, and is not uncommon in dry elevated pastures.

Lin. *Arboreum,* Tree-Flax; with wedge-shaped leaves and arborescent stem; is a native of the Levant, but has been admitted to the green-house on account of its beautiful yellow flowers, which grow in succession throughout the summer.

Drosera. *Gen. char.*—Cal. five-cleft, petals five; caps. one-celled, three-valved, superior; many-seeded.

Dros. *Rotundifolia,* Round-leaved Sun-dew; with leaves round, radical, stem branched; perennial; flowers in July and August, and is not uncommon in boggy ground.

Dros. *Longifolia,* Long-leaved Sun-dew; with leaves radical, obovate; in similar places with the former, but less frequent.

Dros. *Anglica,* Great Sun-dew; has nearly the same characters as the preceding, but is furnished with eight styles and a four-valved capsule, is double the size, and a rarer plant.

The upper surface of the leaves of all these species of sun-dew is thinly set with long red hairs, which exude a transparent viscid fluid, especially during bright sunshine. Small insects, which are attracted to the leaves, or alight accidentally upon them, are entangled in the hairs, and destroyed by being enclosed in the leaves, which fold upon them in consequence of the irritation from the motions of the struggling insect.

Crassula. *Gen. char.*—Cal. five-leaved; five petals; and five nectariferous scales at the base of the germen.

Cras. *Coccinea,* Scarlet-flowered Crassula; with ovate, plain, cartilaginous-ciliated leaves, sheathing and united at the base. Native of the Cape, but a splendid inmate of the green-house, on account of the fragrance and rich scarlet of its flowers, which blow during the summer.—*Bot. Mag.* 495. Plate 31. Fig. 5.

The numerous species of crassula are remarkable for succulent leaves; they are chiefly natives of the Cape, and some of them shoot up to the size of small trees.

Order VI. Polygynia.

Myosurus *Minimus,* Mouse-tail. *Gen char.*—Cal. five leaved, with an appendage at the base; petals five, with a tubular nectariferous claw. An annual plant; flowers in May, and sometimes appears in fields of a gravelly soil.

Class VI. Hexandria.

Six Stamens; Six Orders.

Order I. Monogynia.

The genera arranged under this order are the most numerous of the class; they are divided into six sections, and include the splendid liliaceous tribe, which Linnæus has distinguished by the pre-eminent designation of the nobles of the vegetable kingdom.

Bromelia. *Gen char.*—Cor. tripartite; cal. tripartite, superior; a berry.

Brom. *Penguin,* Penguin of Jamaica; with leaves ciliate, spiny, dagger-pointed; raceme terminal. This singular plant is common in the Savannahs, Hexandria.

and on the rocky hills of Jamaica, and is usually employed for making fences; for which purpose it is admirably suited, by its firm leaves, thickly set on the edges with strong bent spines.

Brom. *Ananas*, Pine-apple; with leaves ciliate, spiny, dagger-pointed, and comose or tufted spike. Numerous varieties of this most delicious fruit are cultivated in tropical regions; and, to bring it to any degree of perfection in this country, the powerful heat of the stove is necessary.

Brom. *Karatas*, Silk Grass; with leaves erect, and aggregate, sessile flowers; native of Jamaica. The leaves of this plant grow to the height of five or six feet; and, when the outer rind is scraped off, the silky fibres are soaked in water, afterwards dried in the sun, and then manufactured into ropes and fishing-nets.

Galanthus *Nivalis*, Snowdrop. Cor. superior, six-petaled, the three interior petals shorter, acutely notched; stigma simple. The early appearance of the snowdrop, with its delicate nodding flowers, in February and March, renders it a well known plant.

Narcissus. *Gen. char.*—Cor. superior, six petaled, equal; nectary funnel-shaped, one-leafed, petaliferous; the stamens within the nectary; stigma three-parted.

Nar. *Poeticus*. Common Narcissus; with one-flowered sheath, nectary wheel-shaped, very short membranaceous notched leaves, obtusely keeled, reflected on the margin; said to be a native of some parts of England, but finds a place in every garden, and often varies with double flowers.

Nar. *Pseudo-Narcissus*, Common Daffodil; with one-flowered sheath, and erect bell-shaped nectary, equal in length to the ovate petals; perennial; flowers in March and April; not unfrequent in woods, common in gardens, and varies with double flowers.

Nar. *Jonquilla*, Common Jonquil, a native of Spain, Nar. *Tazetta*, Polyanthus Narcissus, a native of Spain, Portugal, and of the Barbary coast, Nar. *Orientalis*, with its numerous varieties, and other species of this beautiful genus, have been introduced among the ornaments of the flower-garden.

Amaryllis. *Gen. char.*—Cor. six-petaled, irregular; filaments inserted in the throat of the tube, declining, unequal.

Am. *Belladonna*, Belladonna Lily; with many flowered sheath; cor. bell-shaped, equal; supposed to be a native of South America, as it was introduced from Portugal, is frequently cultivated in gardens on account of the beauty and fragrance of its flowers.

Am. *Sarniensis*, Guernsey Lily; with plain linear petals, and the stamens and pistil upright and longer than the corolla; a native of Japan, but is cultivated in the open ground in the island of Guernsey, to which it was introduced by the melancholy accident of the shipwreck of a Dutch or English ship, with some of the roots on board from Japan, before the middle of the 17th century. The roots were cast ashore, buried in the sand, and after a few years, to the surprise and admiration of the inhabitants, exhibited their splendid flowers in all their pomp and beauty. Various other species of Amaryllis have been since introduced, all which are remarkable for their beauty and grandeur; but among them Am. *Vittata*, or Superb Amaryllis, which shoots up its stem to the height of three feet, shines conspicuous.—*Bot. Mag.* 129.

Hexandria.

Allium. *Gen. char.*—Cor. inferior, six-petaled, spreading; spathe two-cleft, many flowered; umbel crowded, stigma simple.

Al. *Ursinum*, Broad-leaved Garlic or Ramsons; with a naked semi-cylindrical stem, and lanceolate leaves on foot-stalks; perennial; flowers in May and June, and is common in woods and moist meadows.

Al. *Vineale*, Crow Garlic; with round-leafed bulbiferous stem, and stamens three-pointed; perennial; flowers in July, and is not uncommon in dry pastures and on old walls.

To the same genus belong Al. *Schœnoprasum*, or Chive Garlick, Al. *Porrum*, the garden leek, and Al. *Cepa*, the cultivated onion.

Agave *Americana*, American Aloe. Cor. superior, six-cleft, limb erect, shorter than the filaments; leaves somewhat compressed, dagger-shaped, spinous, toothed on the edges. This splendid plant is a native of the rocky hills of Jamaica; it is several years before it throws up the flower stem, which, in a vigorous plant, rises to the height of eight or ten, and sometimes, it is said, twenty feet, adorned with a prodigious number of yellow flowers, which render it conspicuous at the distance of many miles. It appears to be viviparous in its native soil; it seldom flowers in the stove in this country; but it is a vulgar mistake that it puts forth its blossoms only once in a hundred years. This seems to depend on the management and state of the plant. Plate 31. Fig. 7.

Hyacinthus. *Gen. char.*—Cor. inferior, six-cleft, somewhat bell-shaped; stamens inserted in the tube.

Hyac. *Nonscriptus*, (*scilla nutans* of Smith,) Wild Hyacinth; with linear leaves, nodding spike, with the flowers reflected at the summit; perennial; flowers in May, and is very common in woods and hedges.

Hyac. *Orientalis*, Garden Hyacinth, with many flowered raceme. This fine ornament of the garden and the parlour is a native of the vicinity of Aleppo and Bagdad, and of the coast of Barbary. It was cultivated in England about the end of the 16th century; and its numerous varieties, with white, red, blue, yellow, double, and semidouble flowers, have been objects of great attention among the Dutch florists. A single root of a rare variety has brought from L.100 to L.200 Sterling. Two thousand varieties are enumerated and named by the Harlem gardeners; and whole acres in the vicinity of that city are occupied in the cultivation of those flowers.

Lilium. *Gen. char.*—Cor. six-petaled, bell-shaped, with a longitudinal nectariferous line, petals channelled at the base.

Lil. *Candidum*, White Lily; with leaves sparse or scattered, bell-shaped corolla, smooth within; supposed to be a native of the Levant, or of Palestine, and is now a very common but splendid ornament of almost every garden, where it varies with double flowers, spotted with purple, and leaves striped or edged with yellow.

Lil. *Bulbiferum*, Orange Lily; with scattered leaves, erect, bell-shaped corolla, rough within. Native of Austria and Italy, but now one of the most common garden flowers.

Lil. *Chalcedonicum*, Chalcedonian Lily, or Scarlet Martagon; with lanceolate scattered leaves, flowers reflected, corolla bent back. Native of Persia, and common in gardens.

Various other species of lily are cultivated, among which *Lilium Martagon*, Turks' cap Lily, and *Lilium Superbum*, Superb Lily, the former a native of Germany and the latter of Carolina, are stately and magnificent plants.

Tulipa. *Gen. char.*—Cor. six-petaled, bell-shaped, inferior, no style; caps. three-celled.

Tul. *Sylvestris*, Wild Tulip; with a single, slightly nodding flower, and lanceolate leaves. Native of several parts of England; perennial, and flowers in April.

Tul. *Suaveolens*, Early dwarf Tulip; with lanceolate glaucous leaves, nearly equal in height to the one-flowered stem. This beautiful little tulip is supposed to be a native of the south of Europe, is well known under the name of *Duc Van Thol*, and is deservedly admired on account of its rich colours and sweet scent.

Tul. *Gesneriana*, which in its specific name commemorates Conrad Gesner, a botanist of the 16th century, and a systematic writer on the classification of plants, is a native of Turkey, and is the parent of all those rich varieties, amounting now to not fewer than a thousand, which command so much of the florist's care and admiration; Tul. *Breyniana*, a native of the Cape, with stem supporting from two to six flowers, is yet rare in the gardens of this country.

Berberis, *Vulgaris*, Barberry. *Gen. char.*—Cal. six-leaved, petals six, with two glands at the claws; no style; berry superior, two-seeded; a shrubby plant; flowers in May and June, and is common in hedges and among brushwood. The irritability of the stamens of the barberry is very remarkable.

Order II. Digynia.

Oryza *Sativa*, Rice. Cal. one-flowered, glume two-valved; Cor. two-valved; one oblong seed.—One species only of this valuable plant is known; the stem rises to the height of four or five feet, and the flowers are arranged on a terminating panicle. Rice is most successfully raised in those situations which admit of flooding with water; it is extensively cultivated in China and India, where it forms the chief food of the native inhabitants, as well as in Carolina, from all of which places it is imported into Europe, and forms a wholesome, nutritious aliment.

Order III. Trigynia.

Rumex. *Gen. char.*—Cal. three-leaved; petals three, meeting together; one triangular, superior, naked seed; stigmas much divided.

Rum. *Crispus*, Curled Dock; with all the valves ovate, entire; leaves lanceolate, waved, acute. Perennial; flowers in June and July, and is very common in waste places and by way-sides.

Rum. *Obtusifolius*, Broad-leaved Dock; radical leaves, heart-shaped, blunt; stem roughish. Common.

Rum. *Digynus*, Mountain Sorrel; the leaves radical, kidney-shaped, and on foot-stalks. Common on the mountains of Wales and Scotland, and sometimes used as salad.

Rum. *Acetosa*, Common Sorrel; with diœcious flowers, and oblong arrow-headed leaves; common in meadows and pastures.

Rum. *Acetosella*, Sheep's Sorrel; with diœcious flowers, and lanceolate halberd-shaped leaves; very common in barren pastures.

Order IV. Tetragynia.

Petiveria *Alliacea*, Guinea Henweed. Cal. four-leaved, no corolla; style lateral; one seed. This plant is a native of Jamaica and South America, is remarkably acrid, and, when chewed, produces great heat in the mouth; the Guinea hen is extremely fond of it, from which it derives its name; and it communicates the taste of garlic to the milk, and an unpleasant flavour even to the flesh of cattle that feed upon it. The Peruvians employed it as a charm, and fancied that its effects were very powerful and extensive; but its use was prohibited by the Spaniards, either from a desire to discourage such superstitions, or from an apprehension that they were injurious to their power.

Order V. Polygynia.

Alisma. *Gen. char.*—Cal. three-leaved; petals three; several seed-vessels.

Al. *Plantago*, Great Water Plantain; with acute ovate leaves, and bluntly-triangular capsules; common on the banks of lakes and rivers.

Al. *Ranunculoides*, Small Water Plantain; with linear lanceolate leaves, and incurvated five-angled capsules. In similar places with the preceding, but less common.

Class VII. Heptandria.

With Seven Stamens, and divided into Four Orders.

Order I. Monogynia.

Trientalis *Europæa*, Chickweed Wintergreen. Cal. seven-leaved; cor. seven-cleft, equal, plain; a dry berry. Common in woods on the sides of mountains in the north of England and in Scotland.

Disandra *Prostrata*, Trailing Disandra. Cal. five or seven parted; cor. wheel-shaped, five or seven parted; caps. two-celled, many-seeded. Native of Madeira, but not uncommon in the greenhouse and parlour, where its trailing stems, peltate leaves, and yellow flowers, render it an agreeable object. It is sometimes called by mistake a geranium. Plate 31. Fig. 8.

Æsculus *Hippocastanum*, Horse-Chesnut. Cal. five-toothed; cor. five-petaled, unequal; caps. three-celled. The horse-chesnut, which recommends itself to attention as a fine spreading tree, with large digitated leaves, and beautiful spikes of flowers, is a good example of this class and order, although the irregularity of the corolla may produce some difficulty to the young botanist.

To the second order, Digynia, belongs *Limeum*, an African genus of plants: Under the third, Tetragynia, is included *Saururus*, or Lizard's Tail, a native of Virginia: And the fourth order, Heptagynia, has only one genus, *Septas*, and one species. It is a native of the Cape of Good Hope, and is nearly allied to the genus *Crassula;* but it is remarkable in having seven segments in the calyx, seven petals, and seven germens.

Class VIII. Octandria.

Eight Stamens, and divided into Four Orders.

Order I. Monogynia.

Tropæolum *Majus*, Greater Indian Cress. *Gen. char.*—Cal. one-leafed, with a spur; petals five, unequal; berries three, dry; leaves peltate, five-lobed. Native of Peru, introduced about the end of the 17th century, and now one of the most common, although not the least splendid ornaments of the flower-garden, where it sometimes varies in colour, and with double flowers.

Epilobium. *Gen. char.*—Cal. four-cleft; petals four; caps. oblong, inferior; seeds downy.

Ep. *Angustifolium*, Rosebay Willow-herb, or French Willow; with scattered linear lanceolate leaves, unequal flowers, and declining stamens. Native of Britain, and common in gardens and shrubberies.

Ep. *Hirsutum*, Great Hairy Willow-herb, or Codlins and Cream; with leaves half embracing, ovate, lanceolate; stem much branched. Common in moist and shady places, as in the ditches round Edinburgh.

Ep. *Tetragonum*, Square-stalked Willow-herb; with lanceolate toothed leaves, and square stem. On the sides of ditches, and in marshy places.

Oenothera. *Gen. char.*—Cal. four-cleft; petals four; caps. cylindrical, inferior; seeds naked.

Oen. *Pumila*, Dwarf Oenothera, or Tree Primrose; with lanceolate, obtuse, and smooth leaves. Native of North America, and the smallest of this tribe of plants; is a hardy perennial, and continues to blossom through the summer.

Oen. *Longiflora*, Long-flowered Tree Primrose; with toothed leaves, simple hairy stem, and two-lobed petals. Native of Buenos Ayres, and rising to more than five feet in height; forms a fine ornament to an open border, where it flowers from July to October. *Bot. Mag.* 365.

Oen. *Biennis*, Biennial Tree Primrose; has been long an inhabitant of the garden, and possesses the remarkable peculiarity, as well as the preceding, and some other species, of expanding its flowers only in the night, contrary to the ordinary habits of plants in general.

Fuchsia *Coccinea*, Scarlet Fuchsia. *Gen. char.* Cal. one-leafed, coloured, very large; petals four; berry inferior, four-celled, many seeded. *Spec. char.*—Leaves opposite, ovate, toothed; obovate obtuse petals. Native of Chili; and although now one of the most common ornaments of the greenhouse and parlour, still recommends itself by the beauty of its rich, pendulous blossoms; the calyx and stamens are of a fine scarlet; and the corolla, as if apprehensive that exposure to light would injure its deep purple colour, is folded up within the cap. This fine plant is of humble growth, as it has been hitherto treated in this country; but in its native soil it probably attains a considerable magnitude; and in the splendid conservatory of Sir Robert Liston at Millburn Tower, near Edinburgh, it has reached the height of more than eight feet, and exhibits the gayest profusion of flowers and shining black berries. The scarlet fuchsia, planted in a sheltered border, survives the winter; the stems decay, but shoot up vigorously in the spring, and are clothed with flowers during the summer. Plate 32. Fig. 8.

Erica. *Gen. char.*—Cal. four-leaved; cor. four-cleft; stamens inserted in the receptacle; caps. superior, four-celled, many-seeded.

Er. *Vulgaris*, Common Heath or Ling; with anthers included, bearded style protruded; cor. four-parted, shorter than the calyx, with leaves opposite. Very common in moorlands and woods.

Er. *Tetralix*, Cross-leaved Heath; with four ciliated leaves in the whorl; flowers capitate. In moist moorlands.

Er. *Cinerea*, Fine-leaved Heath; with ternate leaves; also common in moorlands.

The three species now described are natives of every part of Britain.

Er. *Vagans*, Cornish Heath, is common in Cornwall; and *Er. Dabœcii*, Irish Heath, is a native of Ireland. But of this beautiful tribe of plants, nearly 300 species, chiefly natives of the Cape of Good Hope, and many of them pre-eminent for the elegance of their form, and the beauty of their flowers, are cultivated in this country.

Daphne. *Gen. char.*—Cal. four-cleft, having the appearance of a corolla inclosing the stamen; berry one-seeded.

Daph. *Mezereum*, Mezereon, or Spurge Olive; with sessile, ternate flowers on the stem; leaves lanceolate, deciduous. In woods in England, and common in gardens, where it is well known by the expansion of its fine red flowers before the leaves.

Daph. *Laghetto*, Lace-bark Tree; is a native of Jamaica, and grows to the height of 20 feet on rocky hills; but it is remarkable for the thickness of its bark, which is divisible into 20 or 30 thin layers as fine and white as gauze or lace, from which it has derived its name. Caps and ruffles, it is said, have been made of it; and a governor of Jamaica presented Charles II. with a cravat of the bark of this tree.

Order II. Digynia.

Moehringia *Muscosa*, Mountain Chickweed.—Cal. four-leaved; cor. four-petaled; caps. one-celled. Native of Germany, but not uncommon in gardens, where it sometimes has the common name

Octandria.

of Moss-plant, from the leaves forming a close turf like some mosses.

Order III. Trigynia.

Paullinia *Curassavica*, Supple Jack. Cal. four-leaved; cor. four-petaled; caps. three-celled, one-seeded; leaves biternate; the foot-stalks margined, and branches unarmed. Common in the woods of Jamaica, and rises to a great height, with its slender, woody, and flexible stems on the neighbouring trees. Deprived of its bark, it is well known in this country by the use of the smaller twigs, as riding-switches, and the larger pieces as walking-sticks.

Coccoloba *Uvifera*, Sea-side Grape. Cal. five-parted; cor. none; berry cup-like, one-seeded; leaves round, smooth. Common on the sandy shores of Jamaica, grows to a considerable magnitude, and the berries, about the size of the common grape, are sometimes eaten. Another species, Coc. *Pubescens*, is also a native of Jamaica, is sometimes seen in the stove in this country, and is remarkable for its large downy leaves.

Polygonum. Cal. five-parted, coloured, in place of a corolla, persistent; seed one, superior, angular, covered with the calyx; the stamens and pistils varying in number.

Pol. *Amphibium*, Amphibious Persicaria; with flowers of five stamens and two pistils, spike ovate. Not uncommon in ditches and pools, where it may be readily distinguished by its floating leaves and elegant flower-spike.

Pol. *Persicaria*, Spotted Persicaria; flowers with six stamens, and ovate oblong spikes. Common in ditches and moist places.

Pol. *Bistorta*, Great Bistort, or Snake-weed; with a simple leafy stem, and ovate waved leaves. In meadows and pastures, and common in gardens.

Pol. *Aviculare*, Knot-Grass; with axillary flowers, elliptical lance-shaped leaves, rough on the margin, and herbaceous procumbent stem; in waste places, and by way-sides, very common. The number of stamens, eight, and pistils, three, is complete in this species.

Order IV. Tetragynia.

Paris *Quadrifolia*, Herb Paris, or True Love. Cal. four-leaved; petals four, narrower; berry superior, four-celled; anthers attached to the middle of the filaments. Perennial; flowers in May; grows in shady woods, but is a very rare plant. No habitat is specified in the Flora Britannica, and we have met with it only in two places in Scotland, in the woods on the banks of the Cart, a little above Cathcart castle, near Glasgow, and in a shady wood on the banks of the same river, not far from the bridge on the road from Hawkhead, the seat of the Earl of Glasgow, to the old castle of Crookstone near Paisley.

Adoxa *Moschatellina*, Tuberous Moschatel. Cal. two or three-cleft; cor. four or five-cleft, superior; caps. four or five-celled. A small perennial plant; common in woods and shady hedges, and flowers early in spring.

Enneandria.

Class IX. Enneandria.

Nine Stamens; Three Orders.

Order I. Monogynia.

Laurus. *Gen. char.*—Cal. none; cor. six petaled, in the form of a calyx; berry one-seeded; glands of the nectary furnished with two bristles.

Under this genus are arranged many valuable plants, natives of different regions, among which are enumerated,

Laur. *Nobilis*, or Bay Tree, with spear-shaped, nerved, stiff leaves; a native of Italy, and deservedly admired on account of its evergreen foliage and fine red berries.

Laur. *Cassia*, the Cassia Tree; a native of the East; of which both buds and bark, having the properties of cinnamon, are employed as a spice, and for medical purposes.

Laur. *Chloroxylon*, Green Heart, or Cogwood Tree of Jamaica, with three-nerved, ovate, coriaceous leaves; a native of the mountainous parts of that island, and affording a strong durable wood, which is employed in machinery.

Laur. *Cinnamomum*, Cinnamon Tree; with ovate, oblong, three-nerved leaves. This precious tree, the bark of which yields the well-known and universally esteemed spice, is a native of Ceylon, and rises to the height of twenty or thirty feet. The cinnamon is obtained from the inner bark of the tree, and the strongest and best kind is got from the small branches, which do not exceed an inch in diameter. The leaves and other parts of the tree yield the same delicate flavour as the bark, and may be employed for similar purposes.

In Ceylon the cinnamon trees are barked twice in the year; the first, or great harvest, continues from April to August, and the second, or small harvest, from November to January. Branches of three years old are lopped off; and the epidermis, or outer bark, being removed by scraping with a knife, the twigs are ripped up lengthwise, and the bark is gradually loosened till it slips off. Smaller tubes or quills of peeled bark are inserted into those of larger diameter, which, as they dry, roll up closer together. They are afterwards tied up in bundles, and are ready for the market.

The Dutch long monopolized the trade of cinnamon. The first introduction of this plant into a British colony was in 1782, when some cinnamon trees were found in a collection of East India plants in a French ship from the Isle of France to St Domingo, which was captured by admiral Rodney. The collection was carried to Jamaica, and one of the cinnamon trees was planted in Mr East's noble garden in Liguanea, and another in the botanic garden at Bath. From them many hundreds of young trees, which now thrive in almost every part of the island, were produced; and it is gratifying to learn that they yield bark of the very finest quality.

Laur. *Camphora*, Camphor Tree; with lanceolate, ovate, triple-nerved leaves, the nerves extending to the point of the leaf. The camphor tree is a native of Japan, and grows to a large size, but is not a stranger to the green-house in this country. A fine specimen of this tree has been long an inhabitant of the botanic garden at Edinburgh; and this, as well as the sassafras tree, another species of the same genus, are among the fine collection in Sir Robert Liston's conservatory.

Every part of the tree yields camphor. The root, trunk, and branches, are cut into small pieces, and introduced into a still with water. The head of the still is lined with straw, and heat being applied, the water is kept boiling for two days, during which the camphor rises and attaches itself to the straw. In this state it is called crude camphor, which was formerly imported, and farther purified, by the Dutch.

Laur. *Persea*, Avocado, or Alligator Pear; with ovate, coriaceous, transversely veined leaves; said to be a native of South America, but very generally cultivated in the West Indies. The pulpy fruit of this tree is the celebrated *vegetable marrow*, a soft substance, of a consistence between butter and marrow, and is a mild nutritious food, agreeable to most palates, and greedily sought after by almost all animals. The eatable part is included between a thick rind and a large hard seed. It is commonly eaten with pepper and salt; and sometimes wine, sugar, or lime-juice, is added.

Anacardium *Occidentale*, Cashew-nut Tree. Cal. five-parted; a tenth stamen is without an anther; seed, a nut attached to a fleshy receptacle. This tree grows in a spreading form to the height of 20 feet; the cashew apple, which is reddish, or yellow, or streaked, is about the size and form of a French pippin, and is full of acid juice, which is employed as an ingredient in punch. The nut grows attached to the end of the fruit, and its covering contains a very acrid oil, which produces blisters on the skin, and is sometimes employed as a caustic.

Order II. Trigynia.

Rheum *Palmatum*, Rhubarb. Cal. none; cor. six-cleft; one triangular seed. This species, which has large palmated leaves, is a native of China, and yields the true rhubarb of the shops; although it is probable that the roots of more than one species are brought into commerce. The cultivation of this species has succeeded well in different parts of Britain; and the roots are considered by many to possess medical virtues equal to the imported rhubarb. Several other species of rhubarb are known; and of the stems of *rheum rhaponticum*, which sometimes is called English, and sometimes Scotch Rhubarb, an excellent tart is made.

Order III. Hexagynia.

Butomus *Umbellatus*, Flowering Rush. Cal. none; petals six; caps. six, superior; many-seeded. This plant, which is the only species of the order and genus, is a fine ornament to the banks of rivers and pools in England, where it is a native.

Class X. Decandria.

Ten Stamens; Five Orders.

Order I. Monogynia.

Sophora. *Gen. char.*—Cal. five-toothed, gibbous above; cor. papilionaceous, with wings the length of the vexillum.

Soph. *Tetraptera*, Winged-podded Sophora; with pinnated leaves, and pods furnished with four membranaceous wings. Native of New Zealand, where it was discovered by Sir Joseph Banks, and cultivated in green-houses in this country; in Chelsea gardens it has produced a magnificent profusion of pendulous yellow flowers, remarkable for the richness and brilliancy of their colouring.—*Bot. Mag.* 167.

Soph. *Monosperma*, Red Bead-tree; with leaves unequally pinnated, leaflets five-paired; pod one-seeded. Native of Jamaica and of the other West India islands; rises 10 feet high, and produces beautiful round scarlet seeds, marked with a black spot, which are brought to this country and employed for ornamental purposes.

Cæsalpinia. *Gen. char.*—Cal. with unequal segments; cor. with five petals, the lowest the largest.

Cæs. *Braziletto*, Brazil Wood; with leaves much divided, leaflets oval. Native of Jamaica and Brazil, produces a fine pyramidal spike of white flowers, beautifully variegated with red; is a strong durable wood, susceptible of a good polish, and affords the famous Braziletto wood, extensively employed in dyeing.

Hæmatoxylon *Campeachianum*, Logwood, or Campeachy-wood; stigma of the pistil notched at the summit, pod with boat-shaped valves. Native of the bay of Campeachy, from which the specific name is derived; it rises to the height of 16 or 20 feet, and is furnished with pinnated leaves, each having four pairs of small leaflets; has been introduced into Jamaica, where it grows luxuriantly, and is employed as a fence against cattle; but the wood of this tree is better known as it is imported into Europe for the purpose of a dye-stuff.

Swietenia. *Gen. char.*—Nectary tubular, ten-toothed; caps. noody, five-valved; seeds imbricated, with a membranous border.

Swiet. *Mahagoni*, Mahogany Tree; with pinnated leaves, four-paired, panicle axillary. Native of Jamaica, Cuba, and the Spanish Main; becomes a magnificent tree, and has been long celebrated as a commercial commodity, and for its extensive use in cabinet-work; it thrives well in almost every soil, but the wood of the closest texture, and most beautifully veined, is obtained from trees which grow on rocky ground.

The mahogany tree has been met with in Jamaica more than 100 feet in height; and one which was cut down in the parish of St Elizabeth measured 12 feet in diameter; it produced nearly L.400 Sterling to the proprietor, but it must be observed that this

Decandria.

happened in the time of the American war, when the price was high. Mahogany is now scarce in Jamaica, and is rarely met with, excepting in mountainous situations, from which it is with difficulty brought to convenient shipping-places for the market.

The introduction of mahogany into England took place about the commencement of the 18th century, and its first application was to the ignoble purpose of a candle-box. A Captain Gibbons, in the West India trade, brought home some planks of it as ballast, and presented them to his brother, a physician in London, who was then building a house, but the wood being found too hard for the tools of the carpenters, was laid aside as useless. Mrs Gibbons, desirous that the wood might not be lost, employed Mr Wollaston, cabinet-maker, to make a candle-box; he executed the task, but complained also of the hardness of the wood. Dr Gibbons then proposed to have a bureau made of the same wood; its agreeable colour and fine polish were universally admired; and, among the rest of his friends who crowded to see it, the Duchess of Buckingham was so delighted with its beauty, that she requested as much wood as would furnish her with a similar piece of furniture; the same cabinet-maker was employed; the fame of mahogany and Mr Wollaston spread far and wide, and the use of this wood soon became general.

The bark of the mahogany tree, as Dr Wright observes, resembles Peruvian bark in colour as well as in taste, but has more bitterness; and it has been employed as a substitute, in the form of powder, of infusion, and of tincture. The bark of another species, *Swietenia Febrifuga*, discovered by Dr Roxburgh in India, possesses similar properties, and has been used for similar purposes.

Guaiacum *Officinale*, Lignumvitæ. Cal. with the two outer segments smaller; caps. fleshy, three or four-celled; leaves angular, pinnated, with two pairs of obtuse leaflets. Native of the south side of Jamaica, to which it is chiefly confined, and rising to the height of forty feet. The wood is solid and ponderous, and affords a fine example of the difference between perfect wood and the alburnum, the former of which is of a yellowish colour, and the latter dark brown. It is extensively employed in machinery and turnery-work; and the gum-resin which exudes from the wounded tree is much used in medicine.

Ruta *Graveolens*, Common Rue. Germen with ten honey-bearing points; caps. five-cleft, five-celled and many-seeded, with supra-decompound leaves; leaflets wedge-shaped. Native of the south of Europe, but common in gardens, and once in great estimation on account of its medical virtues.

Quassia. *Gen. char.*—Cal. five-leaved, petals five, nectary five-leaved; caps. five, two-valved, one-seeded.

Quas. *Amara*, Bitter Quassia; flowers with both stamens and pistils, and leaves pinnated, with an odd leaflet. Native of Surinam, and, with its fine scarlet flowers, is a great ornament to the stove, where it blossoms freely. Three other species, *simaruba*, *excelsa*, and *polygama*, are natives of Jamaica; and from the bark of the roots a very strong bitter, which has been employed in medicine, and as a substitute for hops, is obtained.

Dionaea *Muscipula*, Venus Fly-trap. Cal. five-leaved, petals five, caps. one-celled, and many-seeded. Native of marshy places in South Carolina. The leaves of this singular plant are all radical, and supported on long, winged, succulent, and strongly veined foot-stalks; the leaf itself is composed of two semi-oval lobes, jointed at the back, which permits them to fold together. The sides of the lobes are furnished with a row of cartilaginous ciliæ, which lock into each other when the lobes close. Three very small spines, or bristles, rise in the middle of each lobe in some plants, but in others only two are observed. These spines are the only irritable points of the leaf; every other part may be touched with the point of a needle without the least motion being produced; but the moment it comes in contact with any of the spines the lobes fold together; and, in some experiments which we had lately an opportunity of making on a fine vigorous plant, it seemed that the motion was first communicated to the opposite lobe. The irritability of the spines was first discovered by Mr Edwards, natural history painter, and about the same time by Mr Koenig.

This curious plant thrives well in pots with bog-earth mixed with white sand, and the pot being kept in a pan of water in an airy stove; but it has been known even to succeed better when covered with a glass cylinder, open at top, and placed in the window of a room with a warm aspect. *Bot. Mag.* 785. Plate 32. Fig. 2.

Melastoma. *Gen. char.*—Cal. five-cleft, bell-shaped; petals five, inserted on the calyx; berry five-celled, covered by the calyx.

Mel. *Tomentosa*, Woolly Melastoma, or Indian Currant-Bush; with large subsessile oval leaves, woolly on the under side. Native of Guiana. Plate 32. Fig. 3.

Mel. *Corymbosa*; a native of Africa, is figured in *Bot. Mag.* 904; not fewer than thirty-two species are natives of Jamaica; and sixty species are described, with beautifully coloured figures, in the *Monograph* of this genus by Bonpland, the enterprising companion of Humboldt in his travels in South America, one of the most splendid botanical works which has yet appeared.

The number of stamens varies in the different species from eight to ten; and the nerved structure of the leaves in all the species gives them a striking and very natural character.

Andromeda. *Gen. char.*—Cal. five-parted; cor. ovate, with mouth five-cleft; caps. superior, five-celled.

And. *Polifolia*, Marsh Andromeda, or Wild Rosemary; with aggregated terminal peduncles, and alternate, lanceolate, revolute leaves, glaucous on the lower surface; on peat-bogs in the north of England and south of Scotland.

And. *Arborea*, Tree Andromeda, or Sorrel-Tree; with terminal panicles, the corolla somewhat downy, and elliptical, sharp-pointed, toothed leaves. Native of the Alleghany mountains, in North America, where it is said to grow to the height of fifty or sixty feet; but in the vicinity of London it becomes only a large shrub, with pendulous branches, terminated by long racemes of white flowers. *Bot. Mag.* 905.

Rhododendron. *Gen. char.*—Cal. five-parted; cor. funnel-shaped; stamens bent downwards; caps. five-celled.

Rhod. *Ponticum*, Purple Rhododendron; with shining lanceolate leaves, smooth on both surfaces, and terminal racemes. Native of Gibraltar, and of the south side of Mount Caucasus, but is familiar to the gardens of this country.

Rhod. *Maximum*, Laurel-leaved Rhododendron; with oblong leaves, smooth and discoloured underneath, with an acute reflected margin. Native of North America, where it grows to the height of sixteen feet, and has been introduced into the gardens of this country. *Bot. Mag.* 951.

Kalmia. *Gen. char.*—Cal. five-parted; cor. salver-shaped, with the limb five-horned beneath; caps. five-celled.

Kal. *Latifolia*, Broad-leaved Kalmia; with ovate, elliptical, ternate, and scattered leaves. Native of North America, and now common in the garden.

Kal. *Glauca*, Glaucous Kalmia; with opposite oblong polished leaves, hoary underneath, revolute on the margin, and with terminal corymbs. Native of Newfoundland, but now not uncommon in the garden.

A curious structure is observed in the flowers of this genus; when they first expand the anthers are imbedded in a cavity of the corolla, and, as the flower advances to maturity, they spring up successively; or the same thing may be seen by touching them gently with a sharp point.

Arbutus. *Gen. char.*—Cal. five-parted; cor. ovate, with the mouth five-cleft, pellucid at the base; berry superior, five-celled.

Arb. *Unedo*, Strawberry-tree; with arborescent stem, smooth, obtusely-serrated leaves, terminal panicle, and many-seeded berries. This fine shrub adorns the limestone rocks in the west of Ireland, and is abundant about the lake of Killarney.

Arb. *Alpina*, Black-berried Alpine Arbutus; with procumbent stems, and wrinkled, serrated leaves. Native of some of the higher mountains of the Highlands of Scotland, where it is distinguished by the reticulated veins of the leaves.

Arb. *Uva Ursi*, Red-berried trailing Arbutus; with procumbent stems and entire leaves. Common in the Highlands of Scotland, and near Hexham in Northumberland.

Order II. Digynia.

Hydrangea. *Gen. Char.*—Cal. five-cleft; cor. five-petaled; caps. two-celled, two-beaked, inferior, opening between the styles.

Hyd. *Arborescens*, Shrubby Hydrangea; with a woody stem. A native of Virginia, and long an inhabitant of some gardens in England.

Hyd. *Hortensis*, Garden Hydrangea; with elliptical, serrated, very smooth leaves, and equal stamens. This magnificent plant, which, from being so common, ceases to be admired, is remarkable for the changes in the progress of flowering. The blossoms are at first green, then rose-coloured, and, last of all, green a second time; and the plant which has produced red flowers one year, shall send forth blue flowers the next, although treated in the same manner. It is a native of China and Japan, where it is also cultivated for the sake of its beauty, and was introduced from China to the gardens at Kew in 1790.

Saxifraga. *Gen. Char.*—Cal. five-parted; cor. five-petaled; caps. two-beaked, one-celled, many-seeded.

Sax. *Umbrosa*, London Pride, None-so-pretty; with obovate leaves, and naked paniculated stem. Native of some high mountains in Ireland, and of some parts of England, and one of the most common plants in the flower-garden.

Sax. *Granulata*, White Saxifrage; with kidney-formed, lobed leaves, paniculated stem, and granulated root. Frequent in meadows and pastures of a gravelly soil, and is not uncommon in the garden with double flowers.

Sax. *Hypnoides*, Mossy Saxifrage, or Lady's Cushion; with linear leaves, entire, or three-cleft; on mountainous places, as on Arthur's Seat, Edinburgh.

Sax. *Crassifolia*, Oval-leaved Saxifrage; with oval crenulated leaves, and naked stem. Native of the Alps of Siberia, but common in the garden, and easily distinguished by its large leaves, which are red on the under, and of a fine shining green on the upper surface, and by its tall stem supporting a large bunch of purple pendulous flowers, which appear early in spring.

Sax. *Sarmentosa*, Strawberry Saxifrage; with radical leaves, roundish, heart-shaped, notched, axillary, rooting runners; irregular corolla, and compound raceme. Native of China, but very common as an ornament of the greenhouse and parlour. This species is particularly distinguished by its variegated leaves and the unusual size of the two lowermost pendant petals of the flower. By some unaccountable mistake, it is vulgarly called an Otaheite plant.

Dianthus. *Gen. char.*—Cal. cylindrical, one-leafed, scaly at the base; petals five, furnished with claws; caps. cylindrical, superior, one-celled.

Dian. *Caryophyllus*, Clove, Pink, or Carnation; with solitary flowers, scales of the calyx very short, and somewhat rhomboidal, petals notched, and without beard. Native of England, and found on ancient walls, as on Rochester and Deal castles; and from this species numerous varieties have been obtained by culture.

Dian. *Deltoides*, Maiden Pink; with solitary flowers, scales of the calyx about two, ovate lanceolate acute leaves, slightly downy; in sandy and gravelly pastures, as in the north side of the King's park at Edinburgh.

Dian. *Barbatus*, Bearded Pink, or Sweet William; with fasciculated, aggregated flowers; scales of the calyx ovate, awl-shaped, equal to the tube. Native of Germany, but long an ornament of the flower-garden in this country, where it exhibits endless varieties of colours, and appears occasionally with double flowers.

Decandria.

Dian. *Chinensis*, China or Indian Pink; with solitary flowers, scales of the calyx open, equal to the tube, and corolla notched. Native of China, and, recommended by the brilliancy and variety of its colours, among the annuals of the flower-garden.

Order III. Trigynia.

Stellaria. *Gen. char.*—Cal. five-leaved, spreading; petals five, two-parted; caps. superior, one-celled, many-seeded, six-toothed at the summit.

Stel. *Media*, Common Chickweed; with ovate leaves, and stems procumbent, with an alternate hairy lateral line; an annual; common every where; flowering throughout great part of the year. The number of stamens is observed to vary from ten to five.

Stel. *Holostea*, Greater Stitchwort; with serrulated lanceolate leaves, two-cleft petals, and cal. without nerves; in dry woods and among bushes.

Stel. *Graminea*, or Lesser Stitchwort; with linear, lanceolate, entire leaves, and three-nerved calyx nearly equal to the petals. In pastures and hedges in a dry soil.

Stel. *Nemorum*, Wood Stitchwort; with lower leaves heart-shaped, and with footstalks; upper leaves ovate and sessile. In moist, shady woods, but not very common. It is readily distinguished by its larger leaves and more specious flowers.

Arenaria. *Gen. char.*—Cal. five-leaved, spreading; petals five, entire; caps. superior, one-celled; many-seeded.

Ar. *Peploides*, Sea-chickweed, or Sandwort; with ovate, acute, fleshy leaves; cal. obtuse, and without nerves; perennial; flowers in June and July, and is frequent on sandy shores.

Ar. *Verna*, Vernal Sandwort; with bluntish awl-shaped leaves, obovate petals longer than the three-nerved calyx; perennial; continues in flower from May to August, and is a native of mountainous districts, as on Arthur's Seat, near Edinburgh, and about the mouths of lead-mines in Derbyshire.

Order IV. Pentagynia.

Sedum. *Gen. char.*—Cal. five-cleft; cor. five-petaled; five nectariferous scales at the base of the germen; capsules five, superior.

Sed. *Acre*, Biting Stone-crop, or Wall Pepper; with alternate, subovate, fleshy, gibbous leaves, and trifid leafy cymes; perennial; flowers in June, and is very common on walls, houses, and sandy places.

Sed. *Villosum*, Hairy Stone-crop; with alternate linear, somewhat plain, leaves; slightly hairy footstalks, and upright stem. Perennial; flowers in July, and is found in moist elevated pastures, as in the northern counties of England, and on the banks of the water of Leith, near its sources in the Pentland hills, in Scotland.

Oxalis *Acetosella*, Common Wood Sorrel. Cal. five-leaved; petals five, united by the claws; caps. superior, five-celled, opening at the angles; seeds enclosed in an elastic covering; stem one-flowered; leaves ternate, obcordate, hairy. Perennial; flowers in May, and is common in shady woods.

Agrostemma *Githago*, Corn-Cockle. Cal. one-leafed, leathery; petals five, clawed, with obtuse and divided limb; caps. superior, one-celled, with five-toothed mouth; calyx shaggy, longer than the corolla; petals entire, naked. An annual plant; flowers in June and July, and is common among corn.

Decandria.

Lychnis. *Gen. char.*—Cal. one-leafed, oblong; petals five, clawed; limb often divided; caps. superior, opening, five-toothed; from one to two-celled.

Lych. *Flos-cuculi*, Meadow Lychnis, or Ragged Robin; with four-cleft petals, and one-celled roundish capsule; perennial; flowers in June, and a very common plant in moist meadows.

Lych. *Viscaria*, Red German Catchfly; with undivided petals, and five-celled seed-vessel; perennial; flowers in June, and is found in the fisures of rocks, but is rather a rare plant, although abundant on the rocks of the King's park at Edinburgh.

Lych. *Dioica*, Red or White Campion, as it varies in the colour of its flowers; with diœcious flowers, and one-celled capsule; perennial; continues in flower through the summer, and is common in moist woods and hedges.

Cerastium. *Gen. char.*—Cal. five-leaved; petals two-cleft; caps. superior, opening at the summit, mouth ten-toothed, one-celled.

Cer. *Vulgatum*, Broad-leaved Mouse-ear Chickweed; rough, viscid, with ovate leaves, petals equal to the calyx, and flowers longer than the peduncle; annual; flowers in May, and is common in pastures, waste places, and on walls.

Cer. *Latifolium*, Bruad-leaved Rough Chickweed; with rough elliptical leaves, and terminal, simple, nearly solitary flower-stems; perennial; flowers in June, and is not uncommon on the mountains of Wales and Scotland, as on Benlomond.

Some species of Cerastium are deficient in the parts of fructification, as *Semidecandrum*, which has five stamens, and *Tetrandrum*, which has only four petals and four stamens.

Spergula. *Gen. char.*—Cal. five-leaved, petals five, entire; caps. superior, ovate, one-celled, five-valved.

Sper. *Arvensis*, Corn-Spurrey; with whorled leaves, flower stems reflected, seeds kidney-shaped. Annual; flowers in July and August, and is a troublesome weed in poor exhausted soils.

Sper. *Nodosa*, Knotted Spurrey; with opposite, awl-shaped, smooth leaves; upper leaves fasciculated; calyx without nerve. Perennial; flowers in July and August, and is frequent in moist sandy places.

Order V. Decagynia.

Phytolacca, American Nightshade or Pokeweed; cal. five-leaved, resembling a corolla; cor. none; berry ten-celled.

The species of this genus are natives of America, Africa, and India, and are conveniently distinguished by the variable number of stamens and pistils.

Phyt. *Decandra*, Redweed or Foxglove; with ten stamens and ten styles; a native of Jamaica, where it is very common; it produces reddish berries, which were employed to deepen the colour of red wines; to prevent which a severe edict, even on pain of death, was issued by the King of France. The seeds are used by the negroes for washing linen; they are very bitter, and communicate the same taste to the flesh of birds which feed on them.

Phyt. *Octandra*, Spanish Calalue; flowers with eight stamens and eight styles; native of Jamaica, and cultivated in the kitchen gardens of the island as a palatable green.

Class XI. Dodecandria.

Stamens from 12 to 20. Six Orders.

Order I. Monogynia.

Asarum *Europæum*, Asarabacca. Cal. three-cleft, sitting on the germen; cor. none; stamens twelve; caps. leathery, six-celled, crowned; stigma six-cleft; leaves kidney-formed, obtuse, in pairs. Perennial; flowers in May, and is a native of the woods of the north of England, but rare. The dried root in powder is employed to provoke sneezing and the flow of mucus in the nostrils.

Rhizophora *Mangle*, Mangrove. Cal. four-parted, inferior; cor. four-parted; seed one, club-shaped; a fleshy receptacle; leaves acute. Native of Jamaica, and rises to the height of 30 or 40, and even 50 feet. The Mangrove-tree is generally found on the borders of the sea, in whose waters only it seems to thrive, and in such places as have a soft bottom. The larger branches throw out soft leafless shoots, which bend downward, and in a short time reach the mud, where they strike root, and become supports to the parent tree. The American oyster attaches itself to those branches of the Mangrove tree which dip in the water, and from hence has arisen the fabulous account of this shell fish growing on trees.

Lythrum *Salicaria*, Purple Loose-strife. Cal. twelve-cleft; inferior petals six, inserted in the calyx; caps. two-celled, many seeded; leaves opposite, heart-shaped lanceolate; flowers spiked, with twelve stamens. Perennial; flowers in July and August, and is a fine ornament to marshy places and banks of rivers, where it is most common.

Halesia *Tetraptera*, Four-winged Snowdrop Tree. Cal. four-toothed, superior; cor. four-cleft; nut quadrangular, four-celled; seeds solitary; leaves ovate, pointed, with hairy veins on the lower surface; wings of the seed equal. Native of South Carolina; flowers in April and May, and, from the beauty of its flowers, might be a fine ornament to pleasure grounds in this country. *Bot. Mag.* 910.

Order II. Digynia.

Heliocarpus *Americana*, Sun-seed. Cal. four-leaved; cor. four-petaled; caps. two-celled, one-seeded. Native of Vera Cruz, and remarkable for the fringed or radiated structure of its fruit.

Agrimonia *Eupatoria*, Common Agrimony. Cal. five-toothed, calyculated, or with a double calyx; petals five, inserted in the calyx; seeds two, in the bottom of the calyx; stem leaves pinnated, the odd leaflet with a foot-stalk; seeds rough, with hooked bristles. Perennial; flowers in June and July, and is common in woods and on the borders of fields.

Order III. Trigynia.

Reseda. *Gen. char.*—Cal. one-leaved, divided; cor. with petals, much divided; caps. superior, opening at the summit, one-celled, many-seeded.

Res. *Luteola*, Dyers' Weed, Yellow Weed, or Weld; with lanceolate, entire, plain leaves; cal. four-cleft. Annual; flowers in July, and is not uncommon in waste places and near walls; it is also cultivated on account of the yellow dye which it affords.

Res. *Lutea*, Wild Mignonette, or Base Rocket; with all the leaves three-cleft, the inferior pinnated; cal. six-cleft. Annual or perennial; flowers in July and August, and is not uncommon in dry soils.

Res. *Odorata*, Mignonette; with leaves entire and three-lobed, the calyx equal to the flower; native of Egypt, but a peculiar favourite of the garden and parlour, on account of the sweet fragrance of its flowers.

Euphorbia. *Gen. char.*—Cal. one-leaved, ventricose, inferior; nectaries four or five, attached to the calyx; caps. with a foot-stalk, three-celled.

Euph. *Peplus*, Petty Spurge; with trifid umbel, branches divided into two, leaves entire, obovate, foot-stalked; annual; flowers in July and August, and is very common in cultivated grounds.

Euph. *Exigua*, Dwarf Spurge; umbel trifid, branches divided, leaves linear; annual; flowers in July, and is common among corn.

Euph. *Helioscopia*, Sun Spurge, or Wartwort; umbel five-cleft, leaves serrated, wedge-shaped; annual; flowers in July and August, and is very common in cultivated places.

Order IV. Tetragynia.

To this order belong *Calligonum*, the species of which are natives of Russia and Siberia, and have been illustrated by L'Heritier, *Transact. Linn. Society, Vol. I.*; and *Aponogeton*, the species of which are aquatic plants, and natives of the Cape and of the East Indies. Two genera are arranged under the fifth order; but they are little known, or indistinctly discriminated.

Order VI. Hexandria.

Cephalotus *Follicularis*, Pitcher Plant. This singular plant was discovered by Labillardiere, on the southern shores of New Holland; and it was found by Mr Brown in marshy places in the neighbourhood of King George's sound. The peculiarity of its structure is in certain appendages called ascidia, or pitchers, which are supported by foot-stalks, and are arranged in a circle around the leaves. "The ascidia, or pitchers of Cephalotus," says Mr Brown, "were observed to be in general nearly half filled with a watery fluid, in which great numbers of a small species of ant were frequently found drowned. This fluid, which had a slightly sweet taste, might possibly be in part a secretion of the pitcher itself, but more probably consists merely of rain water received and preserved in it. The lid of the pitcher, in the full grown state, was found either accurately closing its mouth, or having an erect position, and therefore leaving it entirely open; and it is not unlikely that the position of the lid is determined by the state of the atmosphere, or even by other external causes."—Append. to *Flinder's Voyage*. See Plate 32. Fig. 4.

Order VII. Dodecagynia.

Sempervivum. *Gen. char.*—Cal. inferior, twelve-parted; petals twelve; caps. twelve, many-seeded.

Semper. *Tectorum*, Common House-leek; leaves ciliated, with spreading shoots. Perennial; flowers in July, and frequent on houses and walls.

Semp. *Arachnoideum*, Cobweb House-leek; with leaves interwoven with hairs. Native of the Alps of Switzerland, but is not uncommon in gardens. The singular appearance of this plant arises from the woolly tops of the leaves; for as they expand the woolly substance is extended, and exhibits somewhat of the structure of a cobweb.

Class XII. Icosandria.

Twenty or more Stamens on the calyx; Three Orders.

Order I. Monogynia.

Cactus. Cal. superior, one-leaved, imbricated; cor. many-cleft; berry one-celled, many-seeded.

Cact. *Flagelliformis*, Creeping Cereus; with creeping angular shoots; native of the West Indies, but not an unfrequent inmate in the stove or green-house, where it cannot fail to be admired on account of the brilliancy of its flowers.

Numerous other species belong to this genus; they are all natives of warm climates; and on one of them, Cact. *Cochenillifer*, the precious Cochineal insect makes its abode.

Philadelphus *Coronarius*, Mock Orange. Cal. four or five-parted, superior; petals four or five; caps. four or five-celled, many-seeded; leaves somewhat toothed. Supposed to be a native of the south of Europe, but it is now one of the most common shrubs in the garden.

Myrtus. *Gen. char.*—Cal. superior, five-toothed; petals five; berry striated, seven-celled.

Myrt. *Tomentosa*, Woolly-leaved Myrtle; with one-flowered peduncles; leaves triply nerved, woolly on the under surface. A native of China, and is cultivated in the stove in this country, on account of the beauty of its foliage and flowers.

Myrt. *Communis*, the Common Myrtle, a native of Italy, is rarely absent from collections of plants in the green-house or parlour.

Myrt. *Pimenta*, Jamaica Pepper, or Allspice Tree; with oblong lanceolate leaves. Native of the West India islands. This fine tree, which grows spontaneously and abundantly in Jamaica, rises to the height of 30 feet, and is remarkable for the beauty of its leaves, which are of a deep shining green. The Pimenta plantations are chiefly on the north side of the island; and nothing can exceed the fragrance which is exhaled from these spicy groves. Soon after the trees are in blossom the berries are fit for gathering, for they are not suffered to ripen on the tree; they are then collected and spread on a terrace; and being exposed to the sun for about a week, they are ready for the market. A single tree sometimes yields a hundred weight of dried spice; and more than 170,000 lbs. weight are annually exported from Jamaica. The name, *Allspice*, is derived from the smell and taste, resembling that of a mixture of cloves, cinnamon, and nutmegs.

Eucalyptus. Cal. superior, truncated, covered with a lid; no corolla; caps. four-celled, many-seeded. Of this genus nearly 100 species have been discovered; most of them are trees, and some of them rival in height and magnitude the tallest vegetable productions. Eucalyptus *Globulus*, and another species peculiar to the southern extremity of Van Diemen's island, rear their lofty heads 150 feet, and are from ten to twelve feet in diameter. With one exception only, all the species of this genus are confined to New Holland.

Metrosideros *Citrina*, Harsh-leaved Metrosideros. Cal. five-toothed, including the germen; petals five, deciduous; stamens separate, many times longer than the petals; leaves linear, lanceolate, rigid. Native of Botany Bay, but not uncommon in the nurseries about London. The generic name is derived from the hardness of the wood. In the structure of its flowers it is nearly allied to the splendid genus *Melaleuca*; and for all its beauty, it is indebted to the brilliant scarlet colour of its long filaments. *Bot. Mag.* 260; and Plate 32. Fig. 5.

Psidium *Pyriferum*, Guava. Cal. superior, five-cleft; cor. five-petaled; berry one-celled, many-seeded; leaves elliptic, peduncles one-flowered. A common tree in the pastures of Jamaica, growing from eight to twelve feet high; the fruit is eaten raw or stewed with milk, and it affords an excellent marmalade and a richly flavoured jelly.

Psid. *Montanum*, is also a native of Jamaica, and rises to the height of 60 or 70 feet, producing also an agreeable fruit and a valuable wood.

Amygdalus. *Gen. char.*—Cal. inferior, five-cleft; cor. five-petaled; drupe, a nut, marked with pores.

This genus includes the Peach, Amyg. *Persica*, a native of Persia; the Almond-tree, Amyg. *Communis*, which by difference of culture affords bitter and sweet almonds, is a native of Barbary, but is cultivated in the south of Europe; and Dwarf Almond, Amyg. *Nana*, with leaves tapering at the base, a native of Russia and Tartary, and one of the most delicate ornaments of the shrubbery in early spring.

Prunus. *Gen. char.*—Cal. inferior, five-cleft; cor. five-petaled; drupe, with an entire kernel.

Icosandria.

Prun. *Padus*, Bird Cherry; with flowers in pendulous racemes; not uncommon in woods and hedges in Britain, especially in the north of England.

Prun. *Spinosa*, Sloe-tree, or Black Thorn; with solitary peduncles, smooth lanceolate leaves, and spinous branches; common in hedges and among brushwood, and flowers early in the spring.

To this genus belong Bullace-tree, Prun. *Insititia*, with double peduncles, and branches ending in a spine; common in hedges and woods: the Cherry-tree, Prun. *Cerasus*, of which numerous varieties arise from culture: and the Plum-tree, Prun. *Domestica*, of which the varieties are not less numerous.

Order II. Pentagynia.

Mespilus. *Gen. char.*—Cal. five-cleft, petals five, drupe inferior, from two to five-seeded.

Mesp. *Oxyacantha*, Hawthorn, White-thorn, or May; spinous, with obtuse nearly three-cleft, smooth, serrated leaves; flower with two pistils. This plant, of which varieties are produced by culture, is well known for its important application in making living hedges, for which it is admirably fitted by the stiffness of its branches, the sharpness of its thorns, and hardy nature.

Mesp. *Germanica*, Common Medlar; is without spines, has downy leaves, and flowers with five styles; is not uncommon in gardens and shrubberies.

Pyrus. *Gen. char.*—Cal. five-cleft; petals five; pome or apple, inferior, from two to five-celled, seeds two.

Pyr. *Communis*, Pear-tree; with simple serrated leaves, and corymbose peduncles; in woods and hedges; but the cultivated varieties are almost endless.

Pyr. *Malus*, Crab-tree, or Apple-tree; with simple serrated leaves, and simple sessile umbels; native of woods and hedges, and the parent of all the cultivated varieties of the apple.

Pyr. *Aucuparia*, Mountain Ash, Quicken or Roan-tree; with smooth pinnated leaves, leaflets serrated; common in woods and hedges, and deservedly admired for its white flowers in the early summer, and scarlet berries in the autumn.

Mesembryanthemum. *Gen. char.*—Cal. five-cleft, petals numerous, linear; caps. fleshy, inferior, many-seeded.

Mesem. *Dolabriforme*, Hatchet-leaved Fig Marygold; is a native of the Cape, and is easily distinguished by the form of the leaves, of which the specific name is descriptive.

Most of the species belonging to this genus are remarkable for the form or structure of their leaves, and many of them are peculiarly distinguished by the beauty and brilliancy of their flowers. Not fewer than fifty species, chiefly natives of the Cape, have been discovered, one of which Mesem. *Crystallinum*, the ice-plant, is a well known annual.

Spiræa. *Gen. char.*—Cal. five-cleft, petals five, capsules superior, two-valved, many-seeded.

Spir. *Filipendula*, Common Dropwort; with leaves interruptedly pinnated, leaflets uniform, smooth, serrated; not uncommon in dry pastures, and cultivated in the garden, where it varies with double flowers.

Icosandria.

Spir. *Ulmaria*, Meadow-sweet, or Queen of the Meadow; with leaves interruptedly pinnated, woolly underneath; the odd leaflet large and lobed; very common in moist meadows, and on the banks of rivers.

Order III. Polygynia.

Rosa. *Gen. char.*—Cal. pitcher-shaped, five-cleft, fleshy, contracted at the neck; petals five; seeds numerous, attached to the inside of the calyx.

Ros. *Spinosissima*, Burnet Rose; with globular fruit, and smooth peduncles, stem covered with numerous prickles; common on the borders of fields, and among brushwood in a sandy soil.

Ros. *Canina*, Common Dog-rose, Wild Brier, or Hep-tree; with ovate fruit, smooth peduncles, and prickles on the stem hooked; very common in hedges and among brushwood.

Ros. *Rubiginosa*, Sweetbrier, or Eglantine; with ovate fruit, rough peduncles, and prickles on the stem hooked; in mountainous places, but well known in the garden for its charming fragrance.

Numerous other species of the rose have been described, and equally numerous varieties have been produced by culture. The Yellow Rose is a native of Germany; the Moss Rose, supposed by some to be a variety of the Provence, and by others, of the Hundred-leaved Rose; and the China Rose, *Semperflorens*, which is seldom without flowers, is a fine ornament of the green-house and the parlour.

Rubus. *Gen. char.*—Cal. five-cleft, petals five, berry superior, composed of one-seeded acini.

Rub. *Idæus*, Raspberry; with leaves five-pinnated and ternate, woolly underneath, foot-stalks channelled, stem prickly; common in woods, and cultivated in the garden.

Rub. *Fruticosus*, Common Bramble; with leaves about five together, woolly underneath, leaflets foot-stalked, prickles hooked, stem angular, and calyx reflected. One of the most common plants.

Rub. *Chamæmorus*, Mountain Bramble; with simple lobed leaves, one-flowered, unarmed; stem and segments of the calyx ovate; not uncommon on the higher mountains of Scotland, Wales, and the north of England.

Fragaria. *Gen. char.*—Cal. ten-cleft, inferior; petals five; receptacle of the seeds ovate, berry deciduous, seed smooth.

Frag. *Vesca*, Wood Strawberry; with creeping runners; frequent in woods and hedges.

Frag. *Sterilis*; Barren Strawberry; with declining stem and loose flower bearing branches, with about two flowers; common in barren pastures.

Potentilla. *Gen. char.*—Cal. ten-cleft, inferior; petals five; seeds roundish, naked, often wrinkled, attached to a small dry receptacle.

Pot. *Anserina*, Silverweed or Wild Tansy; with pinnated, serrated leaves, silky underneath; creeping stem, one-flowered peduncles; very common in moist meadows and by way-sides.

Pot. *Fruticosa*, Shrubby Cinquefoil; with pinnated leaves, and shrubby stem; said to be a native of Yorkshire, but is commonly cultivated in shrubberies.

Geum. *Gen. char.*—Cal. ten-cleft, inferior; petals five; awn of the seeds bent.

Ge. *Urbanum*, Common Avens, or Herb Bennet; with ternate leaves, erect flowers, and naked, hooked awns; very common in woods and hedges.

Ge. *Rivale*, Water Avens; with radical leaves lyre-shaped, nodding flowers, and feathery twisted awns; common in moist places, and on the banks of rivers.

Calycanthus *Floridus*, Carolina All-spice; cal. one-leaved, pitcher-shaped, with the leaflets coloured; styles very many, with a glandular stigma, interior petals longer; native of Carolina, and has been long in the gardens of this country, where it is kept in the green-house and conservatory. The bark of this plant has an agreeable aromatic odour, from which the name is derived; it seems to approach to the flavour of ginger.

Cal. *Præcox*, Japan All-spice; with the interior petals small; is cultivated in Japan as an ornamental plant, and has been introduced into the gardens of this country, where it is deservedly admired for the vast profusion of its flowers, and the remarkable fragrance, which diffuses to a great distance.—*Bot. Mag.* 466.

Class XIII. Polyandria.

In this class the Stamens amount to twenty or more, and they are inserted in the receptacle. It is divided into Seven Orders.

Order I. Monogynia.

Papaver. *Gen. char.*—Cal. two-leaved; petals four; stigma radiated; caps. superior.

Pap. *Argemone*, Long Rough-headed Poppy; with rough, club-shaped capsules, many-flowered, leafy stem; annual; flowers in July, and is not uncommon in fields.

Pap. *Rhœas*, Red Poppy, or Corn Rose; with smooth, somewhat globular capsules; rough, many-flowered stem; leaves pinatifid. Common among corn, and annual.

Pap. *Somniferum*, White Poppy; with cal. and caps. smooth, leaves glaucous, cut, embracing the stem; annual; and cultivated in the East for supplying the demands of commerce with the valuable drug opium, which is the inspissated milky juice of the capsules.

Cistus. *Gen. char.*—Cal. five-leaved, with the leaflets unequal; petals five; caps. superior, angular, three-valved, many-seeded.

Cist. *Helianthemum*, Common Dwarf Cistus; shrubby, procumbent, with elliptic oblong leaves, hoary underneath; common in dry upland pastures.

Many species of this genus are cultivated in the garden: Among which,

Cist. *Formosus*, or Beautiful Cistus, a native of Portugal, appears conspicuous for its specious flowers.

Capparis *Spinosa*, Caper Bush. Cal. four-leaved; berry with a footstalk. This species is a low, prickly shrub, a native of Italy, the buds of which, preserved in vinegar, are well known under the name of capers.

Sanguinaria *Canadensis*, Canada Puccoon, or Bloodwort. Cal. two-leaved; cor. eight-petaled; pod ovate, one-celled. Native of Canada, and remarkable for the singular structure of its leaves, and the bright red or orange-coloured juice of its roots. It has been long cultivated in this country.

Sarracenia *Flava*, Yellow Side-saddle Flower. Cal. double, three and five-leaved; cor. five-petalled; caps. five-celled; stigma in the form of a shield; leaves tubular, erect; valve contracted at the neck. Common in the swamps of North America. The tubular structure of the leaves of this plant has exercised the ingenuity of physiological botanists; but they have not succeeded in ascertaining its use. Other species are cultivated in this country. *Bot. Mag.* 780, and 849.

Nymphæa. *Gen. char.*—Cal. four or five-leaved; cor. many-petalous; stigma radiated, sessile; berry superior, many-celled.

Nymph. *Lutea*, Yellow Water-lily; with cal. five-leaved, larger than the petals; stigma entire; leaves entire, heart-shaped. Not uncommon in rivers and lakes.

Nym. *Alba*, White Water-lily; with four-leaved calyx, and lobed stigma. Frequent in rivers and lakes, where it is easily recognised by its large white flowers.

Nym. *Lotus*, Egyptian Water-lily, or Lotus; with heart-shaped, very smooth, toothed leaves. Native of Egypt and of the East Indies, and an object of veneration among the inhabitants of both countries. A native of Nepaul, seeing the flowers of this plant in Sir William Jones's study, made prostrations before it. *Bot. Mag.* 797.

Tilia *Europæa*, Lime or Linden Tree. Cal. five-parted; petals five; cap. superior, leathery, angular, five-celled, five-valved, opening at the base. *Spec. char.*—Flowers destitute of nectary, leaves heart-shaped; branches of the veins downy. In woods and hedges.

Corchorus. *Gen. char.*—Cal. five-leaved, length of the corolla, deciduous; caps. about five-celled.

Cor. *Siliquosus*, Podded Broom-weed; with linear compressed capsules, and lanceolate leaves. A native of Jamaica, where it grows to the height of three feet.

Cor. *Olitorius*, Common Jews Mallow; with oblong, ventricose capsules; grows to the height of two feet, and is cultivated as a pot-herb at Aleppo. The Jews boil the leaves, and eat them with their meat.

Cor. *Japonicus*, Japan Broom-weed; with doubly serrated, heart-shaped, acuminated leaves, and smooth round stem; has become, on account of its fine double yellow flowers, a great favourite in the garden and parlour.

Polyandria.

Thea, Tea-tree. *Gen. char.*—Cal. five or six-leaved; petals six or nine; caps. three-celled; seeds solitary. Two species, Thea *Viridis* and Thea *Bohea*, are described as distinct by some botanists, while they are considered by others as only varieties. In the first, or the green tea, the stem is covered with a thin, ash-coloured bark; the leaves are oval, pointed, serrated, and of a deep green. In the bohea, the branches of the foot-stalks of the leaves and flowers are reddish, the leaves are larger, wrinkled, and of a pale bluish green.

The two species or varieties are cultivated in China and Japan. The leaves are collected at three different periods, at the end of February, of March, and April. The leaves of the first crop, which are the smallest, are most esteemed, and, it is said, are reserved for the princes and persons of rank in Japan and China; and the produce of the two later crops is exported to Europe. When the leaves are collected, they are roasted on iron plates to make them shrivel up; and for the same purpose, the better kinds of tea leaves are rolled in the palm of the hand. Before roasting, the Chinese immerse the leaves for a few minutes in boiling water; which process has given rise to a report, that the tea which they export has been already infused.

The varied preparations to which the leaves are subjected, the period of collecting them, the age of the shrub, and the influence of the soil where it is cultivated, produce the varieties of tea in commerce, which are distinguished by different names, and sold at very different prices. The finest and most highly flavoured tea, it is said, is brought from China by land to Petersburgh.

The Chinese method of infusing tea is usually practised in Europe; but the Japanese reduce the dried leaves to fine powder, and add a small spoonful of this powder to a cup of boiling water. Beside the ordinary use of tea, it is perhaps little known, that it is sometimes employed as an addition to the usual ingredients in punch.

Bixa *Orellana*, Annotto. Caps. five-toothed; cor. five-petaled, double; caps. two-valved. Native of the West Indies and of some parts of the American continent; rises to the height of 10 or 12 feet, and yields, from the pulpy matter which covers the seeds, the dye-stuff called Annotto; for the preparation of which, see Annotto.

Order II. Digynia.

Pæonia. *Gen. char.*—Cal. five-leaved; petals five, regular; germens from two to five; no style; caps. many-seeded.

The common Pæony Rose is a splendid ornament of the garden and shrubbery; and Pæonia *Tenuifolia*, Fine-leaved Pæony, with doubly ternate leaves, and leaflets much divided, and naked, produces a specious flower—is a native of the Ukraine, and is found to be a hardy perennial in the gardens of this country.

Order III. Trigynia.

Delphinium. *Gen. char.*—Cal. none; petals five, the uppermost with a spur; nectary two-cleft, spur-shaped behind.

Del. *Consolida*, Field Lark-spur; with solitary capsule, one-leafed nectary, and subdivided stem. Native of some parts of England.

Del. *Ajacis*, Larkspur; is one of the most common annuals in the flower-garden.

Aconitum, or Monk's-hood, of which there are many species, belongs also to this order.

Order IV. Tetragynia.

Under this order are arranged *Wintera Aromatica*, a tree which is a native of South America, and from which is obtained the winter's-bark of the shops.

Order V. Pentagynia.

Aquilegia *Vulgaris*, Common Columbine. Cal. none; petals five; nectaries five, horned, and arranged among the petals; caps. five, distinct. *Spec. char.*—Nectaries bent inwards, scarcely equal to the petals; stem and leaves smooth. In mountainous pastures in England, but, with numerous varieties, cultivated in gardens.

Order VI. Hexagynia.

Stratiotes *Aloides*, Water Aloe, or Water Soldier. Spathe two-leaved; perianth superior; three-cleft; petals three; berry six-celled. *Spec. char.*—Leaves sword-shaped, triangular, prickly, serrated. In marshy places of Lincolnshire and Norfolk.

Order VII. Polygynia.

Anemone. *Gen. char.*—Cal. none; cor. six-petaled; seeds many.

An. *Nemorosa*, Wood Anemone; with one-flowered stem, furnished with a three-leaved involucrum, supported on a foot-stalk. Very common in woods.

An. *Pulsatilla*, Pasque-flower; is also a native of England. An. *Hepatica*, is well known in gardens for its early double flowers; and the beautiful varieties of the Anemone, with double flowers, constitute some of the chief ornaments of the flower-garden.

Ranunculus. *Gen. char.*—Cal. five-leaved; petals from five to eight, with a honey pore within the claws; seeds naked.

Ran. *Flammula*, Lesser Spearwort; with ovate, lanceolate leaves on footstalks; stem declining. Common in marshy places.

Ran. *Lingua*, Great Spearwort; with lanceolate pointed leaves, many flowered, erect stem. In marshy places, but less common.

Ran. *Ficaria*, Pilewort, or Lesser Celandine; with heart-shaped leaves on footstalks. Common in meadows and moist places, and one of the earliest flowers of the spring.

Liriodendron *Tulipifera*, Common Tulip tree. Cal. three-leaved, petals six; seeds imbricated in the form of a cone; leaves lobed. This splendid tree, which, in its native soil in North America, grows to the height of 70 or 80 feet, is successfully cultivated in this country; and one of them, in Mr Ord's garden at Walham-green, near London, is every year covered with blossoms. *Bot. Mag.* 275. See Plate 32. Fig. 6.

Annona. *Gen. char.*—Cal. three-leaved, cor. six-petaled, berry many-seeded, with an imbricated covering.

An. *Muricata,* the Sour Sop, an agreeable acid fruit, and An. *Squamosa,* Sweet Sop, the fruit of which is sweetish, are both natives of Jamaica.

Class XIV. Didynamia.

The plants of this class have four stamens, and the character depends on their unequal length; two of them are long and two short, by which they are distinguished from plants in the fourth class. The corolla is irregular in its form. This class is divided into two orders; the first, *Gymnospermia,* in which the seeds are naked; and the second, *Angiospermia,* in which the seeds are contained in a capsule.

Order I. Gymnospermia.

Ajuga *Reptans,* Common Bugle. *Gen. char.*—The upper lip of the corolla smallest, notched, stamens longer than the upper lip; plant smooth, with single stem, and creeping shoots. Common in woods and moist pastures.

Teucrium *Scorodonia,* Wood-sage. Cor. with no upper-lip, but divided to the base; stamens protruded; leaves heart-shaped, serrated, on footstalks, with lateral racemes; the flowers on one side; erect stem. Common in woods and heaths.

Mentha. *Gen. char.*—Cor. nearly equal, four-cleft, with the broader segment notched; cal. five-cleft; stamens erect and distant.

Of this genus, 12 species, with numerous varieties under most of them, are described as native plants.

Men. *Viridis,* Spearmint; has interrupted spikes; leaves sessile, lanceolate, acute, naked; bracteas bristly, and teeth of the calyx somewhat rough.

Men. *Piperita,* Peppermint; has obtuse spikes, interrupted at the lower part; leaves subovate, smoothish, on footstalks; base of the calyx very smooth. Both are natives, and grow in marshy and moist places, but are extensively cultivated for medical purposes.

Lamium. *Gen. char.*—Cal. five-cleft, with bristly, spreading teeth; cor. upper-lip entire, arched, inferior, two-lobed, inflated, toothed on the margin on each side.

Lam. *Album,* White Dead-nettle; with heart-shaped, serrated, pointed leaves, on footstalks; flowers in whorls. Very common in waste-places about towns.

Lam. *Purpureum,* Red Dead-nettle; with heart-shaped, obtuse leaves, on footstalks; upper leaves crowded together. Annual, and very common in waste places and cultivated grounds.

Stachys. *Gen. char.*—Cal. five-cleft, bearded; cor. upper-lip arched, lower reflected at the sides; middle segment larger, notched; stamens towards the reflected sides, without anthers.

Sta. *Sylvatica,* Hedge Woundwort; with six-flowered whorls, and heart-shaped leaves on footstalks. Common in woods and hedges.

Sta. *Arvensis,* Corn-Woundwort, or Hedge-nettle; with six-flowered whorls, weak stem, and leaves heart-shaped, blunt, crenated, somewhat hairy. Annual, and common in gardens and gravelly soils.

Sta. *Coccinea,* Scarlet Stachys; with six-flowered whorls, and ovate, heart-shaped, crenated leaves, with dilated footstalks. Native of Chili, and seems hardy enough for the climate of this country. *Bot. Mag.* xviii. 666.

Sta. *Lanata,* Woolly Stachys; cultivated in gardens, remarkable for its woolly leaves and stem, and much sought after by the domestic bee.

Prunella. *Gen. char.*—Filaments two-forked at the summit, stigma two-cleft.

Prun. *Vulgaris,* Self-heal; with all the leaves ovate, oblong, and on footstalks. Perennial, and common in meadows and pastures.

Prun. *Grandiflora,* Great-flowered Self-heal; leaves ovate, oblong, slightly serrated, upper lip of the calyx deeply divided into three lobes. Native of the Alps, and, with its fine purple blossoms, is a hardy ornamental plant in the flower-garden. *Bot. Mag.* x. 337.

Order II. Angiospermia.

Rhinanthus *Crista-Galli,* Yellow-rattle, or Horse-rattle. Cal. inflated, four-toothed; shield of the corolla compressed, caps. two-celled, obtuse, compressed; seeds imbricated. *Spec. char.*—Upper lip of the corolla arched; cal. smooth; leaves lanceolate, serrated. Annual, and very common in meadows and pastures.

Euphrasia *Officinalis,* Eye-bright. Cal. cylindrical, four-toothed, equal; upper lip of corolla two-cleft, lower lip three-lobed, with two-cleft segments; anthers furnished with unequal spines. *Spec. char.*—Leaves ovate, minutely toothed. Very common in pastures and heathy grounds.

Antirrhinum. *Gen. char.*—Cal. five-parted, base of the corolla prominent downwards, nectariferous; caps. two-celled.

Ant. *Cymbalaria,* Ivy-leaved Snapdragon; with leaves heart-shaped, five-lobed, alternate, smooth; stems inclining. Perennial; originally introduced from Italy, but common on walls, on the banks of the Thames, about Oxford and Windsor castle, and beginning to appear on the walls near Edinburgh.

Ant. *Linaria,* Common Yellow-toad Flax; with lance-shaped, linear, crowded leaves; stem erect, spiked; cal. smooth, shorter than the nectary. Common in hedges and the borders of fields.

Ant. *Majus,* Great Snapdragon. Cor. without spur; flowers in spikes; cal. obtuse, hairy. Perennial, and a common plant in the flower-garden.

Digitalis *Purpurea,* Purple Foxglove. Cal. five-parted; cor. bell-shaped, five-cleft, inflated, caps. ovate, two-celled, many-seeded. *Spec. char.*—Segments of the calyx ovate, acute; corolla obtuse, upper lip entire; leaves downy. Common in woods and hedges in a sandy or gravelly soil, and varies sometimes with white flowers.

LINNÆA *Borealis*, Two-flowered Linnæa. Cal. double; cal. of the fruit two-leaved, of the flower five-parted, superior; cor. bell-shaped; berry dry, three-celled. This plant, which is intended to commemorate the venerable father of botany, is a native of the northern parts of Europe and America, and has been found in an old fir-wood in Aberdeenshire, in Scotland.

BIGNONIA. *Gen char.*---Cal. five-cleft, cup-formed; throat of corolla bell-shaped, five-cleft, inflated beneath, pod two-celled; seeds with membranaceous wings.

Big. *Radicans*, Ash-leaved Trumpet-flower; with pinnated leaves, leaflets gashed, stem jointed, rooting. Native of North America, and successfully cultivated as an ornamental climber in the neighbourhood of London, mounting to the summit of the loftiest tree, and spreading over the highest wall; and displaying, in August and September, a vast profusion of magnificent flowers. A tree of this species has been long an inhabitant of Chelsea-garden. *Bot. Mag.* xiv. 485. See Plate 32. Fig. 7.

Big. *Longissima*, French Oak, or Trumpet-flower; with simple, oblong-pointed leaves; stem erect, and woolly seeds. Native of Jamaica, and an elegant tree, which rises to the height of 40 feet. Some other species of Bignonia are natives of Jamaica; and it ought to be observed, that the irregular corolla of Big. *Radicans* sometimes assumes a regular form, and five stamens of equal length appear, so that it more properly belongs to the fifth class.

CRESCENTIA. *Gen. char.*—Berry one-celled, with a hard, woody covering; cor. with tube; bell-shaped germen, supported on a foot-stalk.

Cres. *Cujete*, Narrow-leaved Calabash, with wedge-shaped lanceolate leaves. Native of Jamaica; a tree which rises to the height of twenty feet, and is remarkable for the large size of its fruit, which is sometimes a foot in diameter; and the hard woody shell is employed by the negroes as bottles, cups, spoons, and other kitchen utensils. Another species is a native of Jamaica; but the shell of the fruit is so thin that it cannot be applied to the same purposes.

MELIANTHUS. *Gen. char.*—Cal. five-leaved, with the inferior leaf gibbous; petals four, with the nectary beneath the lowest; caps. four-celled.

Two species of this genus have been described, *Major* and *Minor*, both of which are cultivated in this country, and are remarkable for the copious secretion of honey, which is so abundant in the former as to drop from the flowers.

CLASS XV. TETRADYNAMIA.

In this class the character is derived from the unequal length of the stamens, four of which are long and two short, standing opposite to each other. The flowers are composed of four petals, arranged two and two opposite to each other, in the form of a cross, and hence are called cruciform flowers. This class is divided into two orders, characterised by the length of the pod.

ORDER I. SILICULOSA.

The plants belonging to this order have a roundish pod or pouch, which is sometimes called silicle, or little pod.

DRABA *Verna*, Common Whitlow Grass. Silicle entire, with plain valves parallel to the partition; stems naked; petals divided; leaves lanceolate, rough, slightly gashed. Annual, and one of the earliest flowers of the spring; is common on walls and dry pastures.

THLASPI *Bursa-Pastoris*, Common Shepherds' Purse. Silicle notched, obcordate, with valves margined, keeled; an annual plant, flowering through the summer, and everywhere common.

LUNARIA. *Gen. char.*—Silicle on a pedicle with flat valves; style protruded.

To this genus belongs a common plant in the garden, called Moonwort, Honesty, or Satin-flower, which last is derived from the silky appearance of the pod.

Under this order are comprehended *Crambe*, Sea-Cabbage, or Kale; *Lepidium*, one species of which, Lep. *Sativum*, is the well-known Garden Cress; *Cochlearia*, Scurvy Grass; and *Iberis*, Candytuft, remarkable for the inequality of its petals, and familiar in the flower-garden.

ORDER II. SILIQUOSA.

This order is distinguished by the fruit being in the form of a long pod.

CARDAMINE *Pratensis*, Meadow Lady's Smock, Cuckow-flower; pod opening with a spring; valves bent backward, equal to the partition; stigma entire; cal. slightly gaping; a single gland on both sides between the shorter stamens and the calyx; leaves pinnated; radical leaflets, roundish, toothed, those on the stem lanceolate. Perennial, and common in moist pastures, where it exhibits its fine purple or white flowers early in spring.

SISYMBRIUM. *Gen. char.*—Pod opening with upright valves; cal. and cor. spreading.

Sis. *Nasturtium*, Water-Cress; with declining pods, pinnated leaves, leaflets heart-shaped, roundish. Common in rivulets and near springs, and well known as one of the earliest salads for the table.

Sis. *Monense*, Isle of Man Rocket, or Dwarf Sea Rocket; with erect pods; pinnatifid leaves, simple, naked, smooth stems. This plant is very remarkable for its habitat. It is very abundant in dry pastures along the coast of Ayrshire, in Bute and Arran in Scotland, in the Isle of Man and in Cumberland in England, and in Anglesea in Wales, while a single plant has not been discovered in the eastern parts of the kingdom.

ERYSIMUM. *Gen. char.*—Pod straight, exactly square; cal. shut; stigma capitate.

Er. *Officinale*, Common Hedge-Mustard; with pods closely pressed to the stem, leaves runcinated. Annual; flowers in June and July, and is very common in waste places and by way-sides.

Er. *Barbarea*, Yellow Rocket, or Bitter Winter Cress; with inferior leaves lyre-shaped, terminal lobe round, upper leaves obovate, toothed. Perennial; flowers during the summer months, and is common in waste places, by river sides, and hedges, and cultivated in the flower-garden with double flowers.

Er. *Alliaria*, Garlic Hedge-Mustard, or Jack-by-the-Hedge; with heart-shaped leaves. Biennial; flowers in May, and is common in hedges and shady places, where it is at once recognized by the garlic odour which any part of the bruised plant exhales.

Cheiranthus *Fruticulosus*, Wild Wallflower; germen with a small tooth on each side furnished with a gland; cal. closed; seeds plain; leaves lanceolate, acute, hoary on the lower surface; stem shrubby; branches angular. Common on old walls. From the wild variety the wallflower of the garden is different in some of its characters, arising probably from culture.

Brassica. *Gen. char.*—Cal. upright, pod roundish, seeds globular.

To this genus belongs Bras. *Napus*, Rape; Bras. *Rapa*, Turnip; and Bras. *Oleracea*, the Cabbage; and the various species and varieties which are cultivated in gardens.

Sinapis. *Gen. char.*—Cal. spreading; claws of the corolla upright; pod roundish, with a prominent partition.

Three native species belong to this genus; Sin. *Arvensis*, Wild Mustard, or Charlock, with angular pods, a troublesome weed among corn; Sin. *Alba*, White Mustard, with rough pods, which grows in fields and by way-sides, and is sown in the winter and spring as a salad; and Sin. *Nigra*, Common Mustard, with smooth square pods, closely pressed to the stem, which is cultivated on account of its seeds, from which is obtained the mustard of the table.

Raphanus. *Gen. char.*—Cal. closed; pod round, twisted, jointed.

Raph. *Raphanistrum*, Wild Radish, or Jointed Charlock; with jointed, smooth, one-celled pods. Not uncommon among corn.

Raph. *Sativus*, Cultivated Radish; is a familiar plant in the kitchen garden.

Class XVI. Monadelphia.

The character of this class is derived from the stamens being united by their filaments into one tube; and the eight orders into which it is divided are distinguished by the number of stamens.

Order I. Triandria.

Tamarindus *Indica*, the Tamarind Tree; with one pistil; cal. four-parted; petals three; seeds contained in a pod; leaves pinnated, composed of sixteen or eighteen pairs of leaflets. This tree, which is a native of both the Indies, grows to a large size, and sends forth numerous branches, which are thickly set with a beautiful bright green foliage. The pulp, in which the seeds are imbedded within the pod, preserved with sugar, forms the well known acid substance, the tamarinds of the shops.

Sisyrinchium. *Gen. char.*—One pistil; two-leaved spathe; petals six, plain; caps. three-celled, inferior.

Sis. *Bermudiana*, Iris-leaved Sisyrinchium; with sword-shaped leaves; oblong, obcordate, veined petals. Native of Bermudas; and cultivated in the green-house in this country.

Sis. *Gramineum*, Grass-leaved Sisyrinchium; with broad, double edged stem; germen smooth. Native of Virginia, and a hardy perennial in the flower garden.

Ferraria. *Gen. char.*—One pistil; spathe three-leaved; no calyx; petals six, the three outermost broader; caps. three-celled, inferior.

Fer. *Tigridia*, Mexican Ferraria, or Tiger-flower; with folded leaves; corolla broad, pitcher-shaped, inner segments depressed, intersected. This plant, which is a native of Mexico and Peru, is conspicuous for the splendour and rich colouring of its flowers; but it is not less remarkable for its transient existence—all its beauties vanish in a few hours. *Bot. Mag.* xv. 532.

Fer. *Undulata*, Curled Ferraria; with many-flowered stem. A native of the Cape; and, though less splendid, yet it is equally singular and beautiful in its form and appearance, and not less fugacious in the duration of its flowers.

Order II. Pentandria.

Erodium. *Gen. char.*—Cal. five-leaved; cor. five-petaled; nectary five scales; fruit five-seeded, beaked.

Er. *Cicutarium*, Hemlock Stork's-bill; with many flowered peduncles and pinnated leaves, leaflets sessile, pinatifid, gashed; frequent in waste and sandy places.

Er. *Maritimum*, Sea Stork's-bill; with about three flowered peduncles; heart-shaped, gashed, crenated, rough leaves, depressed stems. Not uncommon in sandy places on the sea-coast.

Er. *Incarnatum*, Flesh-coloured Crane's-bill; with few flowered peduncles; leaves three-parted, ternate, or trifid, rough; stem shrubby. Native of the Cape, and one of the most beautiful ornaments of the green-house.

Order III. Heptandria.

Pelargonium. *Gen. char.*—Cal. five-parted, upper segment terminating the inner capillary, nectariferous tube; cor. five-petaled, irregular; fruit five-seeded, beaked.

Pel. *Pinnatum*, Pinnated Crane's-bill; without stem; umbels somewhat compound; leaves pinnated. Native of the Cape, and one of the tenderer species.

Pel. *Bicolor*, Two-coloured Crane's-bill; with many-flowered umbels, and leaves ternate, divided, lobed, and waved. This beautiful species is a fine ornament of the green-house.

Pel. *Peltatum*, Ivy-leaved Crane's-bill; with one-leaved calyx; leaves five-lobed, very entire, smooth; stem shrubby. Native of Africa.

Pel. *Incrassatum*, Fleshy-leaved Crane's-bill; nearly without stem, scape divided, rough; leaves lobed, pinnatifid, smooth. This species is tuberous-rooted, produces beautiful flowers, and is yet rare in this country.—*Bot. Mag.* xx. 761. and Plate 32. Fig. 8.

Order IV. Octandria.

Aitonia *Capensis*, Cape Aitonia. One style; cal. four-parted; cor. four-petaled; berry dry, quadrangular, one-celled, many-seeded. Native of the Cape, and cultivated in the green-house in this country.

Order V. Decandria.

Geranium. *Gen. char.*—Cal. five-leaved; cor. five-petaled; five nectariferous glands; fruit five-seeded, beaked; beaks bent backwards, naked.

Ger. *Robertianum*, Herb Robert, or Stinking Crane's-bill; with two flowered peduncles; pinnatifid, five-angular leaves; cal. with ten angles; caps. wrinkled. Very common in waste-places, and in hedges.

Ger. *Dissectum*, Jagged-leaved Crane's-bill; with two-flowered peduncles; petals notched; leaves divided into five segments; caps. rough; seeds reticulated: Not uncommon in waste places and gravelly soils.

Ger. *Sanguineum*, Bloody Crane's-bill; with one-flowered foot-stalks, five-parted, three-cleft, round leaves; caps. bristly at the summit. Among brushwood in mountainous rocky situations; and, with its deep red specious flowers, rivals some of the exotic species.

The three genera, *Erodium*, *Pelargonium*, and *Geranium*, were formerly included under the latter genus, till they were arranged according to the characters given of each by the celebrated French botanist L'Heritier.

Order VIII. Polyandria.

Bombax *Ceiba*, Cotton Tree. One pistil; cal. simple; caps. five-celled, many-seeded; style undivided; seeds woolly; leaves digitate, with five segments. Native of Jamaica, and one of the largest trees of that island, sometimes rising to the height of 100 feet; the wood is light and porous, and answers well for canoes.

Gossypium *Barbadense*, Cotton Tree. One pistil; cal. exterior, three-cleft; three or four-celled; seeds numerous, imbedded in cotton.

This remarkable plant, which furnishes such abundance of materials for manufactures and commerce, is the spontaneous production of all the tropical regions of Asia, Africa, and America. Different kinds or varieties of cotton are cultivated in the West Indies. Two kinds are particularly distinguished by the planters under the names of *green-seed cotton* and *shrub cotton*; the first is only cultivated for domestic purposes, because it is difficult to separate the seeds from the wool. Several varieties of shrub cotton are described, some of them, perhaps, arising from diversity of soil and culture; such are the common Jamaica cotton, with oblong smooth seeds, and of a strong coarse staple; brown bearded, more productive, and of a finer staple; Nankeen, similar to the preceding, excepting the colour of the wool; French, or small-seed, usually cultivated in St Domingo; and Kidney cotton, so called from the seeds adhering to each other in the pod, and supposed to be the true Brazil cotton.

A valuable kind of cotton, called the Bourbon cotton, was introduced into Jamaica from Bengal in 1795; it is very productive, bears the driest weather, and parts freely from the seed.

The cotton plant, as it is cultivated in Jamaica, is raised from the seed, which is sown from April to October in rows from six to eight feet distant, and the seeds in the row four feet apart. The plants appear in a fortnight, and at the end of three or four months they are pruned or topped, and if the crop be luxuriant the same operation is repeated a second, and even a third time. At the end of five months the beautiful yellow flowers begin to expand; in two months more the pods are formed; and from the seventh to the tenth month they ripen in succession, when they burst open in three partitions, and display the white and glossy down; the wool is then gathered and passed through the *gin*, a machine composed of two small rollers, turning in opposite directions for the purpose of separating the seeds; the wool is afterwards hand-picked to clear it of decayed leaves, broken seeds, and any portions that are stained and damaged in the pod; and being packed in bags of about 200 lb. weight, is ready for the market. The produce of an acre is estimated at from L.200 to L.300, but the crop is very precarious, from numerous accidents to which the plant is exposed. In the first stage of its growth it is attacked by the grub; devoured by the caterpillar in the second; withered by the blast, or destroyed by rains, both in the flowering and ripening state.

Malva. *Gen. char.*—Cal. double, exterior, about three-leaved; caps. numerous, one-seeded, arranged circularly.

Mal. *Sylvestris*, Common Mallow; with herbaceous, erect stem; seven-lobbed, acute leaves; foot-stalks of leaves and flowers hairy. Common in waste places, by way-sides and hedges.

Mal. *Rotundifolia*, Dwarf Mallow; with leaves heart-shaped, round, five or seven lobed; common in waste places and by way-sides.

Mal. *Moschata*, Musk Mallow; with radical leaves kidney-shaped, gashed; stem-leaves five parted; leaflets much divided; calyx hairy. On the borders of fields, but less frequent.

Lavatera. *Gen. char.*—Cal. double, exterior, three cleft; caps. numerous, one-seeded, arranged circularly.

Lav. *Arborea*, Sea-tree Mallow; with woody stem, leaves with seven angles, woolly, and folded. On rocky places near the sea, but rare; on the Bass island and in the frith of Forth, and on Portland island in the British channel. A biennial plant, and grows to the height of six feet.

Lav. *Trimestris*, Annual Lavatera; with rough herbaceous stem, smooth leaves, and one-flowered footstalks; is the well known and shewy annual of the flower garden, where it frequently varies with white flowers.

Hibiscus. *Gen. char.*—Calyx double, exterior, many-leaved; caps. five-celled, many-seeded.

Hib. *Syriacus*, better known by the name of *Althæa Frutex*, is a native of Syria, and one of the finest autumnal ornaments of the flower-garden.

Hibisc. *Elatus*, Mountain Mahoe; with heart-shaped, roundish, entire leaves; one-flowered, very short footstalks; calyx ten-toothed. Frequent in the woods of Jamaica, grows to a large tree, sometimes 60 feet high, and produces specious yellow flowers from the extremities of the branches, from which it has been called tulip tree. The wood is suitable for many valuable purposes, and the bark furnishes an excellent material for ropes. It varies sometimes with red flowers.

Hibisc. *Esculentus*, Eatable Hibiscus, or Ochra of the West Indies; with leaves five-parted, pedate; inner calyx bursting at the side. The capsules of this plant, which are very succulent, are an ingredient in the celebrated pepper-pot, or are eaten by themselves at table, and constitute a rich nourishing food.

Hibisc. *Subdariffa*, Indian Sorrel; with serrated leaves, upper seven parted, lower ovate, undivided. Cultivated in Jamaica on account of the calyx and capsules, which have an agreeable acid taste, and are made into tarts, stewed with milk, or formed into syrup.

Camellia. With imbricated, many-leaved calyx, interior leaflets larger; of which Cam. *Japonica*, or Japan Rose, varying with red and white, single and double flowers, becomes a large tree in the groves and gardens of Japan, and is one of the most splendid inmates of the stove and conservatory in this country,—and *Alcea*, the Holly-hock, with calyx double, the exterior six or nine-cleft, caps. numerous, one-seeded, the varieties of which, with single and double flowers, constitute the shewy ornament of the garden and shrubbery towards the close of summer.

Class XVII. Diadelphia.

The character of this class is derived from the division of the stamens into two parcels. It contains four orders, which are distinguished by the number of their stamens; and the flowers are almost universally papilionaceous.

Under the first order, Pentandria, a single genus, *Monnieria*, a South American plant, with gaping corolla and alternate leaves, is placed.

Order II. Hexandria.

Fumaria. *Gen. char.*—Cal. two-leaved; cor. gaping; filaments two, membranaceous, each with three anthers.

Fum. *Officinalis*, Common Fumitory; with loose spikes, one-seeded, globular, notched pods, segments of the leaflets dilated; very common in fields and gardens.

Order III. Octandria.

Polygala. *Gen. char.*—Cal. five-leaved, two largest leaflets wing-shaped, coloured; pod heart-shaped, two-celled.

Pol. *Vulgaris*, Milk Wort; with flowers crested and in racemes; and leaves linear, lanceolate. Common in warm dry pastures; and its beautiful flowers are blue, violet, and white. To the same genus belong some beautiful species from America and the Cape of Good Hope.

Order IV. Decandria.

In this order the stamens are usually divided into nine in one parcel, with a single one separate, and the genera are distributed into six sections, in the first of which the stamens are all united, as in the common broom; in the second the stigma is downy, as in *Pisum* or Pea, and *Vicia* or Vetch; in the third the pod is nearly two-celled, as in *Astragalus* or Milk-vetch; in the fourth the pod has scarcely more than one seed, as in *Trefolium* or Trefoil; in the fifth the pod is nearly jointed, as in *Hedysarum*; and in the sixth the pod is one-celled and many-seeded.

Spartium *Scoparium*, Common Broom; stigma longitudinal, villous above; filaments united, adhering to the germen; cal. produced downwards; leaves ternate and solitary; branches angular and unarmed. Frequent in dry pastures.

Ulex *Europæus*, Common Furze or Whin. Cal. two-leaved; pod scarcely longer than the calyx; all the stamens united. *Spec. char.*—Teeth of the cal. obtuse; bracteas ovate, loose; branches erect. In barren and heathy soils frequent.

Hedysarum. *Gen. char.*—Pod with one-seeded joints; keel of the cor. transversely obtuse.

Hed. *Onobrychis*, Saint Foin; with pinnated leaves; pods one-seeded; hairy wings of the corolla of the length of the calyx. On hills and chalky pastures in England, and frequently cultivated as food for domestic animals.

Hed. *Gyrans*, Moving Plant; with ternate leaves. A native of the interior parts of Bengal, and remarkable for the constant motion or alternate meeting and receding of the two small appendages or leaflets on each side of the footstalks. This singular motion is continued through the whole day in its native soil; but it is only in the middle of the day that it exerts this power in the stove in this country. Plate 32. Fig. 9.

To this order belong *Lupinus*, Lupine, with the anthers alternately round and oblong, and legume or pod leathery; *Pisum*, in which the style is keeled and woolly above; and of which *Pisum Sativum*, the Garden Pea, furnishes a good example.

Phaseolus, the Kidney Bean; with the keel and style spiral.

Lathyrus; with style plain and woolly above, and upper segments of the calyx one half shorter, of which Lath. *Odoratus*, Sweet Pea, or Painted Lady Pea, is one of the most shewy and common annuals in the flower garden;

Vicia; of which the garden bean, *Vicia Faba*, is a species; with the style bearded under the stigma.

Trifolium, or Trefoil, in which the pod is one or two-seeded, and scarcely longer than the calyx, and the flowers grow in heads.

Indigofera, in which the keel has a tooth on each side, and different species of which are cultivated in the East and West Indies for the purpose of extracting the indigo of commerce; and

Cytisus, with two-lobed calyx, and pod on a footstalk, of which *Cyt. Laburnum*, Common Laburnum, is a well known ornament of the shrubbery.

Class XVIII. Polyadelphia.

In this class the stamens are united by their filaments into more than two parcels; and the three orders into which it is divided are distinguished by the number or insertion of the stamens.

Order I. Dodecandria.

Theobroma *Cacao*, Chocolate-nut Tree. Cal. three-leaved; cor. five-petaled; nectaries five; the number of stamens not distinctly ascertained. The chocolate tree grows to the height of 12 or 16 feet; "it is carefully cultivated," says Dr Wright, "in all the French and Spanish islands in the warmer parts of America. This was formerly the case also in Jamaica; but at present we have only a few straggling trees left as monuments of our indolence. This tree delights in shady places and deep vallies. The leaves are oblong, large, and pointed; the flowers, which are small and pale red, spring from the trunk and large branches; and the pods are oval and pointed. The seeds or nuts are numerous, and curiously enclosed in a white pithy substance. The cacao-nuts being gently parched in an iron pot over the fire, the external covering easily separates; the kernel is levigated on a smooth stone, a little annotto is added, and with a few drops of water is reduced to a mass, and formed into rolls of one lb. weight each. This simple preparation is the most natural and the best." But it ought to be added that the chocolate of the shops is composed of various other ingredients, and perhaps, in some cases, contains but a small proportion of the real powder of the cacao-nut. Plate 33. Fig. 1.

Monsonia *Speciosa*, Large-flowered Monsonia; with five-leaved calyx; cor. five-petaled; stamens 15, united in five divisions; style five-cleft; caps. five-seeded; leaves in fives, and leaflets twice pinnated. This splendid species is a native of the Cape, and may be treated as a hardy green-house plant.

Citrus. *Gen. char.*—Cal. five-toothed; cor. five-petaled; stamens twenty, united into a cylinder; pistil one; berry celled, with a vesicular pulp.

This genus was placed under the following order, Icosandria; but as the filaments are not inserted into the calyx, it belongs more properly, as Dr Smith remarks, to this order.

To this genus belong Cit. *Medica*, the Citron, the rind of which, and the young fruit, are prepared as a sweet-meat; Cit. *Aurantium*, the Orange, of which two varieties, the China and Seville, or the *sweet* and the *bitter*, are well known; Cit. *Decumana*, the Shaddock, which produces a fruit equal in size to a man's head, and eaten, like olives, to give a zest to wine,---and of which the forbidden fruit, as it is called in Jamaica, is supposed to be a variety. To these may be added lime and lemon trees, accounted by some as varieties, but, from the diversity of their appearance and fruit, might be properly regarded as different species.

Order II. Icosandria.

In this order the stamens are numerous, and their filaments are inserted into the calyx.

Melaleuca. *Gen. char.*—Cal. five-parted, superior; cor. five-petaled; caps. half covered with a berried calyx. Of this splendid tribe of plants, which are remarkable for the length and rich colours of the filaments, several species are successfully cultivated in the conservatories of this country; they are chiefly natives of New Holland.

Mel. *Leucadendron*, the Cajeput Tree; the dried leaves of which afford, by distillation, an essential oil used in medicine, is a native of mountainous places in Amboyna.

Order III. Polyandria.

In this order the stamens are unconnected with the calyx.

Hypericum. *Gen. char.*—Cal. five-parted, inferior; petals five; filaments in three or five divisions, united at the base; caps. many-seeded.

Hyp. *Androsæmum*, Tutsan or Park Leaves; with flowers having three pistils; berried capsules, and double-edged shrubby stem; not uncommon in woods, and with its large yellow flowers is a conspicuous ornament in the garden.

Hyp. *Quadrangulum*, Square St John's Wort; is frequent on the banks of rivers and moist meadows, where it is easily distinguished by its specific character; and Hyp. *Perforatum*, Perforated St John's Wort, is common in hedges and woods, and is distinguished by its double-edged stem and obtuse leaves, marked with pellucid spots.

Class XIX. Syngenesia.

In this class the anthers are united into a tube, and the flowers are compound; that is, each flower consists of a number of small flowers called florets. The structure of the florets varies in different plants; sometimes each floret is furnished with perfect stamens and pistil, and brings its seed to maturity; sometimes the florets of the disk are perfect or united, while those of the margin have pistils only, but they all produce perfect seed; sometimes the florets of the disk are perfect or united, but those of the margins have neither pistils nor stamens; in other cases the florets of the disk have stamens only, and those of the margin have pistils only; and in others, several flowers, either simple or compound, but with united tubular anthers, and with a partial calyx, are all included in one general calyx. These differences are the foundation of the five orders of this class.

Order I. Polygamia Æqualis.

The character of this order is derived from each floret having perfect stamens and pistil, and producing ripe seed. Some other differences in the structure of the florets give rise to the distribution of the genera of this order into three sections. Under the first section are included those which have the florets all ligulate or strap-shaped, and which are denominated by Tournefort, semiflosculous; their flowers are generally yellow, sometimes blue, and rarely reddish; they expand in a morning, and close towards noon, or in cloudy weather; and their herbage, when bruised, affords a bitter milky fluid. Of this section common dandelion, goats'-beard, and hawk-weed, are good examples. In the second section the flowers are globose, or grow in heads, and the florets are all tubular, five-cleft, and spreading, as in *Carduus*, Thistle, and *Arctium*, Burdock. In the third section the flowers are discoid, the florets are all tubular and regular, forming a flat or conical surface, as in *Bidens*, Bur Marygold, and *Santolina*, Sea-cotton Weed.

Leontodon. *Gen. char.*—Receptacle naked; cal. imbricated, down, simple, on foot-stalks.

Leon. *Taraxacum*, Common Dandelion; with the exterior scales of the calyx reflected, leaves runcinated, toothed, smooth; very common in meadows, pastures, and waste places.

Leon. *Palustre*, Marsh Dandelion; with leaves sinuated, and sometimes slightly downy; in moist meadows and marshy places.

Hieracium. *Gen. char.*—Recept. naked, dotted; cal. imbricate, ovate; down, simple, sessile.

Hier. *Pilosella*, Mouse-ear Hawkweed; with elliptical entire leaves, woolly underneath, creeping runners, and one-flowered naked stem; very common in dry pastures.

Hier. *Subaudum*, Shrubby Broad-leaved Hawkweed; with many-flowered erect stem, and ovate lanceolate leaves. In woods and rough stoney places.

Arctium *Lappa*, Burdock. Cal. globular, scales bent inwards, and hooked at the summit; leaves heart-shaped, unarmed, and on foot-stalks. Very common by way-sides and in waste places.

Carduus. *Gen. char.*—Cal. inflated, imbricated, with spinous scales; recept. hairy, down falling off.

Car. *Lanceolatus*, Spear Thistle; with decurrent, pinnatifid, rough leaves, segments divaricate, or alternately pointing in different directions. Common in waste places and by way-sides.

Car. *Arvensis*, Creeping Thistle; with sessile, pinnatifid, spinous leaves, stem paniculated; cal. ovate, furnished with spines, down feathery. Very common in fields and by way-sides.

Car. *Marianus*, Milk Thistle; with leaves embracing the stem, spinous, radical, leaves pinnatifid; scales of the calyx leafy, prickly on the margin. In waste places, where it is easily known by its fine green leaves, beautifully marked with white veins.

Eupatorium *Cannabinum*, Hemp Agrimony; recept. naked, down rough; cal. imbricated, oblong; style half two-cleft, protruded; leaves digitate. In wet places on the banks of rivers.

Order II. Polygamia Superflua.

The genera belonging to this order are divided into three sections; discoid, or without strap-shaped florets; florets half tubular, and nearly two-lipped; and radiate flowers. To the first section belong *Tanacetum*, Tansey; *Artemisia*, Wormwood; and *Gnaphalium*, Cudweed: To the second, *Perdicium*, a rare foreign genus, which is the only example: And the following having radiant flowers, or the marginal floret strap-shaped, come under the third section.

Bellis *Perennis*, Common Daisy; recept. naked, conical; no down; cal. hemispherical, with equal scales; seeds obovate; flower-stem naked; root creeping. Very common in meadows and pastures.

Chrysanthemum. *Gen. char.*—Recept. naked, no down; cal. hemispherical, imbricated, with scales dilated at the margin, and membranaceous.

Chrys. *Leucanthemum*, Great White Ox-eye; with leaves embracing the stem; oblong, obtuse, gashed, pinnatifid at the base; radical leaves obovate, and on footstalks. Common in fields and pastures, and is easily distinguished by its specious white flowers.

Chrys. *Segetum*, Yellow Ox-eye, or Corn Marygold; with stem embracing leaves, divided into segments above, toothed at the base; common among corn, especially in a sandy soil. The corn fields in Scotland were at one time so overrun with this plant, that laws were enacted obliging the inhabitants to eradicate it from their grounds, and penalties were inflicted on those who neglected it. Similar regulations were established in Denmark.

Chrys. *Indicum*, Indian Ox-eye Daisy; with simple ovate, sinuated, angular, serrated leaves. This beautiful species, which is much cultivated in China and Japan, is highly ornamental to the green-house and parlour in the winter season, when it shews its fine double, tubular, or quilled flowers, and is not less admired for the fragrance of its leaves.

Chrys. *Tricolor*, Three-coloured Ox-eye Daisy; with double pinnatifid leaves; leaflets linear, distant, bent backward; stem branching, erect. Supposed to be a native of Barbary, and introduced into Britain in 1798, and is an annual of easy culture. Plate 33. Fig 2.

To this order belong *Solidago*, Golden-rod; *Senecio*, Groundsel; *Tussilago*, Colt's foot; *Aster*, Starwort; *Anthemis*, Camomile; and *Achillea*, Sneezewort; different species of which are indigenous, and most of them common.

Gynandria.

ORDER III. POLYGAMIA FRUSTRANEA.

In this order the florets of the disk are perfect or united, and those of the margin have neither pistils nor stamens.

CENTAUREA. *Gen. char.*—Recept. bristly, down simple; rays funnel-shaped, longer than those of the disk, and irregular.

Cent. *Nigra*, Black or Lesser Knapweed; with the scales of the calyx ovate, and with erect capillary cilia; lower leaves lyre-shaped, angular; upper leaves ovate. Common in pastures and by way-sides.

Cent. *Cyanus*, Corn Blue-bottle; with the scales of the calyx serrated; leaves linear, entire; lower leaves toothed. Common among corn.

RUDBECKIA. *Gen. char.*—Recept. chaffy, conical; down with a four-toothed margin; cal. with a double series of scales.

Rud. *Purpurea*, Purple Rudbeckia; with lanceolate-ovate leaves, alternate, undivided, and petals of the ray two-cleft. Native of Carolina and Virginia, but cultivated in the open ground in this country. Plate 33. Fig. 3.

HELIANTHUS. *Gen. char.*—Recept. chaffy; down awned; cal. ragged.

Hel. *Multiflorus*, Many-flowered Sun-flower; with inferior leaves heart-shaped, three-nerved; upper leaves ovate. Native of North America, and a hardy perennial in the gardens of this country.

Hel. *Annuus*, Common Sun-flower; is a well known and shewy annual in every garden; and Hel. *Tuberosus*, Jerusalem Artichoke, is sometimes cultivated for the sake of its tuberous roots, which are eaten like potatoes.

ORDER IV. POLYGAMIA NECESSARIA.

In this order the florets of the disk have only stamens, and those of the margin have pistils only.

CALENDULA *Officinalis*, Garden Marygold, in which the receptacle is naked, there is no down, and the seeds are membranaceous, is an example of this order.

ORDER V. POLYGAMIA SEGREGATA.

In this order, several flowers, either simple or compound, but with united tubular anthers and a partial calyx, are included in a general calyx.

ECHINOPS *Ritro*, Small Globe Thistle; perianth one-flowered; recept. bristly; down obsolete; head globular; leaves pinnatifid, smooth on the upper surface. Native of Siberia and Southern Europe, but has been long cultivated in the gardens of Britain. Plate 33. Fig. 4.

CLASS XX. GYNANDRIA.

In this class the stamens are inserted either upon the style or germen. Linnæus divided the class into nine orders, the character of which is taken from the number of stamens; but succeeding botanists have abolished some of these orders, and some have abolished the whole class, and referred the plants included under it to other classes. Without going over the whole of the orders, a few examples will be sufficient to illustrate the class.

Gynandria.

ORDER I. DIANDRIA.

ORCHIS. *Gen. char.*—Nectary horn-shaped, placed behind the flower.

Or. *Bifolia*, Butterfly Orchis; with undivided bulbs; lip of the nectary lanceolate, entire; horn very long, and lateral petals spreading. In woods and moist places, with a clay soil.

Or. *Maculata*, Spotted Orchis; with palmated, divaricate roots; horn of the nectary shorter than the germen; lip three-lobed, plain; petals spreading. Common in moist meadows and pastures.

OPHRYS. *Gen. char.*—Nectary slightly keel-shaped underneath, deflected.

Oph. *Ovata*, Common Twayblade; with fibrous roots; two-leaved stem; leaves elliptical; lip of the nectary linear, two-cleft. In woods, meadows, and pastures.

Oph. *Corallorhiza*, Coral-rooted Ophrys; with branching, winding, divaricate roots; stem sheathed, without leaves; lip of the nectary undivided. A rare plant, observed by Lightfoot in Ross-shire, and lately discovered near Ravelrig, five miles from Edinburgh.

CYPRIPEDIUM. *Gen. char.*—Nectary two-lipped, lower lip ventricose, inflated, hollow.

Cyp. *Calceolus*, Ladies Slipper; with fibrous roots; leafy stem; petals four, lanceolate, pointed; upper lip elliptical, channelled. In woody places in the north of England, but rare.

Cyp. *Parviflorum*, Yellow Ladies Slipper; with lateral petals, linear, twisted, and longer than the nectary, which is without veins. Native of North America. See Plate 33. Fig. 5.

LIMODORUM. *Gen. char.*—Nectary one-leaved, concave, raised on a footstalk within the lowest petal.

Lim. *Tuberosum*, Tuberous-rooted Limodorum; with bearded, thin, spiked flowers. Native of marshy places in South Carolina; was accidentally introduced into England in 1788, along with bog-earth brought over with some plants of Venus fly-trap. The roots of limodorum were discovered by Mr James Smith, a zealous and excellent botanist, at that time gardener to Mr Curtis, now nurseryman at Monkwood in Ayrshire.

Lim. *Altum*, Tall Limodorum, or Jamaica Saloup; with beardless flowers, and spike in the form of a panicle. Native of Jamaica, where it grows in the cooler parts of the mountains. Two other species are natives of the same island.

EPIDENDRUM. *Gen. char.*—Nectary waved, oblique, reflected.

Epi. *Sinense*, Chinese Epidendrum; with sword-shaped, striated, radical leaves; petals nearly equal; nectary bent-back, spotted; and bractea a little shorter than the germen. Native of China, and cultivated in the stove in this country. Plate 33. Fig. 6.

Epi. *Vanilla*, Vanilla; leaves ovate, oblong, nerved, sessile; tendrils spiral. Native of Jamaica, and cultivated on account of the seeds, which have an agreeable aromatic odour, and are employed to give a flavour to chocolate, and as a perfume to snuff and other substances. Many other species of the same genus are natives of Jamaica.

Order III. Tetrandria.

Nepenthes *Distillatoria*; one pistil; cal. four-parted; no corolla; caps. four-celled. This singular plant, a native of Ceylon, is remarkable for the peculiar structure of its leaves, each of which terminate in a kind of close shut tube, like a tankard, and is furnished with a lid or covering, which contains water, supposed to be secreted through the footstalk. Small worms and insects are found dead in the tube; and a little animal like a shrimp, which is met with alive, is supposed to feed on them.

Order IV. Pentandria.

Passiflora. *Gen. char.*—Three pistils; cal. five-parted; cor. five-petaled; nectary in the form of a crown; berry on a footstalk.

Pass. *Cærulea*, Common Passion-flower; with entire, palmated leaves. Native of the Brazils, and cultivated in the green-house in this country.

Pass. *Alata*, Winged Passion-flower; with undivided entire leaves; membranaceous square stem. Native of the West Indies, and cultivated in the stove on account of the beauty of its flowers.

Pass. *Serratifolia*, Notched-leaved Passion-flower; with undivided, ovate, serrated leaves. Native of Surinam, and has been admitted into the stove, for the sake both of the beauty and fragrance of its flowers. Plate 33. Fig. 7.

Pass. *Quadrangularis*, Four-angled Passion-flower, or Granadilla; leaves oval, subcordate, smooth; stem square, membranaceous. Native of Jamaica, and one of the largest and most beautiful of this splendid tribe of plants. It is cultivated in that island, both on account of its excellent fruit, which contains a rich pulp, with an agreeable odour and pleasant acid taste, and for forming arbours, for which it is well calculated by its thick foliage and highly ornamental flowers.

Pass. *Maliformis*, Apple-formed Passion-flower, or Water Lemon, the fruit of which furnishes food to the wild hogs; and Pass. *Murucuja*, Bull-hoof, the flowers of which, infused in wine or spirits, are employed as a narcotic,---are also natives of Jamaica.

Class XXI. Monœcia.

In this class the stamens and pistils are in separate flowers, but both grow on the same plant. The characters of the orders are taken from the number of stamens, the connection of the filaments, or of the anthers, and their insertion on the style or germen. In describing the genera belonging to this class, as there are two sets of flowers, the one bearing stamens and the other pistils, separate descriptions are necessary. The first or the flowers with stamens are denoted by (1), and the flowers with pistils by (2).

Monandria.

Zannichellia. (1) Cal. none, cor. none. (2) Cal. one-leafed, cor. none, pistils four, seeds four.

Zan. *Palustris*, Horned Pond-weed; with square-celled anther, and stigmas very entire. Native of Britain, and found in ditches and pools.

Artocarpus, Bread-fruit Tree. (1) Cal. two-valved, cor none. (2) Cal. none, cor. none, one style; drupe many-celled.

Art. *Incisa*; Notch-leaved; with gashed leaves; is the celebrated bread-fruit tree; a native of Otaheite and other South-sea islands, which was introduced into Jamaica in the year 1793. Three hundred trees were brought from Otaheite by captain Bligh in the ship Providence, and distributed to different places, from which they have spread to every part of the island.

When the fruit of this tree is used as bread, it is collected before it is quite ripe, roasted in an oven, and the rind being scraped off, the inside, which is soft and white, is eaten, and is found to be a nutritious substance.

The bread-fruit tree was alluded to by Dampier, lord Anson, captain Cook, and other voyagers, as a production of the Ladrone and Philippine islands, and of Otaheite and some of the neighbouring islands; and from the opinion that was formed of its valuable qualities, the Bounty, commanded by captain Bligh, was dispatched by the British government in 1787 to collect plants to be transported to the colonies in the West Indies. A mutiny of the crew, who seized the ship, and carried it back to Otaheite, frustrated for a time this beneficial scheme; and it was not till 1793, as already alluded to, that the plan was successfully accomplished.

Several varieties of the bread-fruit tree are known in its native soil; and another species, with entire leaves, was also introduced at the same time with the first into Jamaica, and is now very generally cultivated in that island.

Diandria.

Lemna. *Gen. char.*—(1) One-leafed, cor. none. (2) Cal. one-leafed, cor. none; style one; caps. many-seeded.

Lem. *Trisulca*, Ivy-leaved Duckweed; with lanceolate proliferous leaves, on footstalks. In ditches and pools.

Lem. *Minor*, Lesser Duckweed; with sessile leaves, plain on both sides, and solitary roots. Very common in ditches and in pools.

Triandria.

Sparganium. *Gen. char.*—(1) Cal. three-leaved, cor. none. (2) Cal. three-leaved; drupe dry, one-seeded.

Spar. *Ramosum*, Branched Bur-reed; with leaves three-cornered at the base, concave at the sides; common peduncle branched; stigma linear. Frequent in lakes and on the banks of rivers.

Spar. *Simplex*, Unbranched Upright Bur-reed; with leaves triangular at the base, plain at the sides, and the common peduncle simple. In lakes.

Carex. (1) An imbricated catkin, cal. one-valved glume; cor. none. (2) Imbricated catkin; cal. one-valved glume; cor. none; stigmas two or three; seed inclosed in an inflated coat.

Car. *Ovalis*, Oval-spiked Carex; with about six oval spikes, alternately approaching; glumes lance-shaped, equal to the seed-coat. In marshes and moist meadows.

Car. *Remota*, Remote Carex; with single distant, nearly sessile spikes; bracteas very long, exceeding the stem; seed-coat nearly entire. In moist woods and wet shady ditches.

Car. *Arenaria*, Sea-Carex; with the spikelets crowded; bracteas scaly; stem triangular; leaves plain. Abundant in sandy places near the shore.

Car. *Sylvatica*, Pendulous Wood-Carex; with sheaths one-half shorter than the peduncle; spikes thread-shaped, loose, nodding; fruit ovate, triangular, beaked. Frequent in woods; rises to the height of two or three feet, and is furnished with an upright, leafy, smooth, triangular stem.

Car. *Flava*, Yellow Carex; with shortened sheaths nearly equal to the peduncle; spikes producing pistils, roundish; fruit beaked, deflected, stem smooth. Frequent in marshy places.

Car. *Præcox*, Vernal Carex; with shortened sheaths nearly equal to the peduncle; spikes ovate, approaching; glumes slightly dagger-shaped; fruit roundish, woolly. Common on heaths and dry pastures.

Car. *Pilulifera*, Round-headed Carex; without sheaths; spikes with pistils, sessile, crowded, roundish; glumes slightly dagger-shaped; fruit roundish, hairy. Frequent in pastures and heaths.

Of this extensive genus, fifty-two species are elegantly described in the *Flora Britannica*. The attentive study of these descriptions, and the careful comparison with the living specimens, cannot fail to improve the learned botanist in the knowledge of the discriminating characters of this curious tribe of plants.

Typha. *Gen. char.*---(1) Catkin cylindrical; anthers about three on a common filament. (2) Catkin cylindrical; seed one, with a downy footstalk.

Typha *Latifolia*, Great Cat's-tail, or Reed-mace; with the leaves nearly sword-shaped, and spikes producing anthers and pistils, approaching each other. Not uncommon in lakes and ditches.

Typha *Angustifolia*, Lesser Cat's-tail, or Reed-mace; with leaves semi-cylindrical, plain, equal to the stem; the anther and pistil bearing spike distant. In ditches and lakes, but less frequent. In the middle of Woolwich common.

Hernandia. *Gen. char.*—(1) Cal. three-parted; cor. three-petaled. (2) Cal. truncated; cor. six-petaled; drupe hollow.

Hern. *Sonora*, Whistling Jack-in-a-box; with heart-shaped, peltate leaves. Native of the East and West Indies. A lofty tree, and remarkable for the singular structure of the fruit. The external covering is much larger than the contained seed; and through a small opening the wind being freely admitted, when it blows strong, the reverberated sound produced within the hollow capsule is heard at a great distance, and is sometimes alarming to travellers.

From this sonorous whistling noise, the trivial name of Jack-in-a-box is derived.

Tetrandria.

Urtica. (1) Cal. four-leaved; cor. none; rudiment of the germen cup-formed. (2) Cal. two-leaved; cor. none; seed one, superior, shining.

Urt. *Urens*, Small Nettle; with opposite elliptical, about five-nerved leaves; racemes nearly simple. Very common in cultivated places.

Urt. *Dioica*, Great Nettle; with leaves opposite, heart-shaped, racemes much branched, double, flowers sometimes diœcious. Common in waste places and hedges.

Buxus. *Gen. char.*—(1) Cal. three-leaved, petals two, with the rudiment of a germen. (2) Cal. four-leaved, petals three, styles three, caps. three-beaked, three-celled.

Bux. *Sempervirens*, Box-tree; on some of the chalk hills in England, and well known, as it is employed as edgings of borders, for which it is well fitted by its evergreen leaves. The close texture of the wood, and the fine polish of which it is susceptible, render its use extensive for the purpose of turnery.

Betula. *Gen. char.*—(1) Cal. scale of the catkin one-leafed, three-cleft, three-flowered; cor. four-parted. (2) Cal. scale of the catkin one-leafed, nearly three-cleft, two-flowered; styles two, seeds compressed.

Bet. *Alba*, Common Birch; with ovate-pointed, serrated, smoothish leaves; common in woods. In the beautiful variety with pendulous branches, from which it is called the weeping birch, the leaves are quite smooth.

Bet. *Nana*, Dwarf Birch; with notched roundish leaves; native of elevated marshy places in Scotland, and rises only to the height of three feet.

Bet. *Alnus*, Common Alder; with branching peduncles, leaves roundish, wedge-shaped, serrated, viscid; common in marshy places.

Morus. *Gen. char.*—(1) Cal. four-parted; cor. none. (2) Cal. four-leaved; cor. none; styles two, seed one, berried.

Mor. *Tinctoria*, Fustic-tree; with oblong leaves, lengthened on one side, and axillary spines. Native of Jamaica, and remarkable for its quick growth, rising to the height of 30 or 40 feet in eight or ten years; the timber is of an excellent quality, and it furnishes the valuable dye-stuff, fustic.

Mor. *Alba*, White Mulberry; a native of China, is extensively cultivated for the sake of its leaves as food for silkworms; grows in Britain.

Mor. *Rubra*, Red Mulberry, a native of Virginia, is cultivated for the same purpose; Mor. *Nigra*, Black Mulberry, is a native of Persia, with dark red fruit, from which wine is made; and Mor. *Papyri-*

fera, Paper Mulberry, a native of Japan and the South sea islands, affords materials for paper and cloth from its bark.

Pentandria.

Amaranthus. *Gen. char.*—(1) Proper calyx three-leaved; cor. none; stamens from three to five. (2) Proper calyx three-leaved; cor. none; styles three; caps. one-celled, cut round; seed one.

Am. *Blitum*, Wild Amaranth; with lateral heads; flowers three-cleft, triandrous; leaves ovate, stem spreading. In cultivated places in some parts of England.

Am. *Spinosus*, Prickly Calalue; with compound terminal racemes, and short prickles under the leaves; a common plant in Jamaica, and frequently employed as a wholesome and agreeable vegetable.

Polyandria.

Fagus. *Gen. char.*—(1) Cal. bell-shaped, five-cleft; cor. none; stamens from five to twelve. (2) Cal. four-cleft; cor. none; styles two or three, three-cleft; seeds two or three, covered with a leathery muricated calyx.

Fag. *Castanea*, Chesnut-tree; with lance-shaped, sharp-pointed, serrated leaves; and the prickles of the fruit compound, interwoven. In woods in England; sometimes grows to a very large size; and a tree in Gloucestershire is supposed to be more than a thousand years old.

Fag. *Sylvatica*, Beech-tree; with leaves ovate and indistinctly serrated; common in woods and hedges, and well known for its use as a close fence.

Quercus. *Gen. char.*—(1) Cal. bell-shaped, lobed; cor. none; stamens from five to ten. (2) Cal. bell-shaped, entire, rough; cor. none; style one; stigmas three; nut superior, leathery, one-seeded.

Quer. *Robur*, Common British Oak; with deciduous, oblong, indented leaves, broader at the summit, indentations acute, lobes obtuse, and peduncles lengthened; common in woods.

The oak in a favourable situation attains a prodigious size. The trunk of an oak in Shropshire, mentioned by Lightfoot, measured in circumference 68 feet, or nearly 23 feet in diameter; and another in Yorkshire measured 48 feet in circumference, or 16 feet in diameter.

Various other species of oak are natives of the south of Europe and of North America.

Quer. *Suber*, grows abundantly in Italy, the south of France, Spain, and Portugal, and furnishes the well known substance cork, of so much importance in domestic economy. The cork-tree is an evergreen, with ovate, oblong, undivided, serrated leaves, slightly downy underneath. Cork is a singular substance, which is produced on the cuticle. The trees are barked for the first time before they are 20 years old, but the best cork is obtained from the oldest trees; and after every peeling the succeeding bark is of a better quality. They are generally peeled once in eight or ten years, and this operation so far from being injurious, contributes to their growth and vigour; for it is observed that those trees which are not stripped of the bark, in a few years begin to decay, and in the course of 50 or 60 years a whole plantation is destroyed; but those trees that are regularly barked, live and thrive more than 200 years.

When the cork is stripped off, an exudation of a reddish brown colour immediately takes place; and of the excreted matter, as it acquires consistency by the action of the air, the succeeding layer of cork is formed. The uses of cork are too familiar to require enumeration.

Quer. *Cerris*, Gall Oak; with smooth, oval, serrated leaves. This tree, which is a native of Asia Minor, from the Bosphorus to Syria, and from the shores of the Archipelago to the frontiers of Persia, seldom attains the height of more than six feet, and more frequently appears in the form of a shrub. The galls are produced on the shoots of the young branches, and the best are those which are collected before the escape of the insect to which their production is owing. Those which are perforated are less fit for the purpose of dye-stuff, and are known in commerce by the name of white galls; but the black or green galls are heavier, and therefore more valuable.

Juglans. *Gen. char.*—(1) Catkin imbricated; cor. six-cleft; stamens about 18. (2) Cal. four-cleft; cor. four-petaled; styles two, drupe leathery.

Jug. *Regia*, Walnut-tree; with alternate, oval, sessile, entire leaves; native of Asia, and cultivated throughout the warmer and more temperate regions of Europe, on account of its fruit, which is extensively employed in its green state, as a pickle, and when ripe furnishes the well known walnuts of commerce.

Corylus. *Gen. char.*—(1) Cal. scale of the catkin three-cleft; cor. none; stamens eight. (2) Cal. two-cleft, ragged; cor. none; styles two; nut ovate, smooth, one-celled, covered with a leathery inflated calyx.

Cor. *Avellana*, Hazel-nut Tree; with ovate, obtuse stipulæ, roundish, heart-shaped, pointed leaves, and small branches hairy; common in woods and hedges.

Cor. *Colurna*, Constantinople Hazel; is much cultivated in some of the Greek islands on account of the excellence of its nuts, which are greatly esteemed in the Turkish metropolis, from which probably the trivial name is derived. The bark of this species produces a fungous substance, similar to the cork of the oak.

Calla. *Gen. char.*—A plain spathe; the spadix, or flower stem, covered with florets; cal. none; petals none; berries many-seeded.

Cal. *Æthiopica*, Ethiopian Calla; with arrow-headed, heart-shaped leaves; native of the Cape, of the sides of rivulets in St Helena, and of the ditches in India, and is now common in the green-house and parlour of this country.

Arum. *Gen. char.*—Spathe one-leaved, convoluted at the base; spadix or flower-spike cylindrical, naked above; flowers below producing pistils, and those in the middle stamens; berries one-celled.

Ar. *Maculatum*, Cuckow-pint or Wake-robin; with halberd-shaped, entire leaves; spadix or flower-spike club-shaped, blunt. Not uncommon in hedges and among brushwood.

Ar. *Triphyllum*, Zebra-flowered Arum; with trifoliate leaves, leaflets oval-pointed. Native of North America; is the largest and most beautiful of the genus, and has been introduced into the gardens of this country. *Bot. Mag.* xxiv. 950.

Monadelphia.

Pinus. *Gen. char.*—(1) Cal. scale of the catkin peltate; cor. none; anthers sessile, attached to the scales. (2) Cal. scale of the catkin two-flowered; cor. none; nut one-celled, winged.

Pin. *Sylvestris*, Scotch Fir; with double, rigid, linear, acute leaves; younger cones on foot-stalks bent back; summit of the anthers small. Not uncommon in the elevated districts of Scotland, and the only species indigenous to the island.

Pin. *Cedrus*, the Cedar Pine; Pin. *Larix*, the Larch-tree; Pin. *Picea*, the Pitch Pine, and some other species,—are natives of other parts of Europe, of the north of Asia, or of America.

Ricinus. *Gen. char.*—(1) Cal. five-parted, cor. none, stamens numerous. (2) Cal. three-parted, cor. none, styles three, caps. three-celled.

Ric. *Communis*, Common Oil-nut Tree; with deeply divided leaves. This plant, which has been long known by the trivial name of *Palma Christi*, is cultivated in the West Indies for the sake of its seeds. The growth is so rapid that it attains the full size of fifteen, and even twenty feet, in a single year. From the seeds, or nuts, the castor oil, so much employed in medicine, is obtained, either by expression, when it is said to be cold-drawn, and is esteemed of the best quality; or by boiling, the product of which brings an inferior price.

Ric. *Inermis*, Unarmed Oil-nut Tree; with peltate, somewhat palmated, serrated leaves, and unarmed fruit. A native of the Spanish West Indies, and much cultivated in Jamaica, because the nuts are larger and more productive, and the quality of the oil equal to the former. Excepting in the fruit being destitute of prickles, this plant resembles the other so closely that it is regarded rather as a variety than a distinct species.

Jatropha. *Gen. char.*—(1) Cal. none; cor. five-cleft; stamens ten. (2) Cal. none; cor. five-petaled; styles three; caps. three-celled.

Jat. *Manihot*, Bitter Cassada; with palmated leaves, lance-shaped, entire lobes. This plant, from the root of which cassada-bread, a very nutritious substance, is obtained, is much cultivated in the West Indies, and rises, by a slender woody stalk, to the height of five or six feet. The roots, which grow to a large size, are fit for use in eight months from the time of planting; being well washed and scraped, they are grated down into a kind of pulpy meal, which is put into strong linen bags, and subjected to powerful pressure, that the whole of the juice may be separated. The meal is then dried in the sun, beaten in a wooden mortar, and passed through a coarse sieve. In this state, and without any addition, it is spread on flat iron plates fixed in a stove. By the action of the heat, the particles of the meal coalesce, and form cakes, which, being thoroughly baked, are eaten as a wholesome and nourishing bread. The juice of the cassada-root is of a poisonous nature, and is extremely noxious to most animals; so that this deleterious substance must be separated before the root can be employed as food.

A variety of this species, called Sweet Cassada, the root of which is free from any deleterious quality, is also cultivated in the West Indies.

Jat. *Gossypifolia*, Cotton-leaved, or Wild Cassada; with five-parted leaves, and ovate, entire, ciliated lobes. Native of Jamaica, and common about the streets of Spanish-Town and Kingston.

Hura. *Gen. char.*—(1) Cal. two-leaved; cor. none; anthers twenty, sessile. (2) Cal. cylindrical; cor. none; one pistil; caps. ten-celled.

Hura *Crepitans*, Crackling Sand-box Tree; A native of Jamaica; rises to the height of thirty or forty feet, and with its large heart-shaped leaves, some of which are near a foot in length, and of a beautiful green, forms a thick shade. The capsule is of a woody texture, round and flat, and regularly divided into cells, each of which contains a single seed. The seeds being taken out, the shell is converted into a sand-box, from which the name is derived; and when the seeds ripen on the tree, the cells burst with an explosive noise, and discharge the seeds to a considerable distance. This is the origin of the specific name.

Hippomane. *Gen. char.*—(1) Cal. two-cleft; cor. none; anthers two-cleft. (2) Cal. three-cleft; cor. none; stigma three-fold; drupe or capsule one-seeded, or three-celled.

Hip. *Mancinella*, Manchineal Tree; with ovate serrated leaves. A native of Jamaica; grows to a large tree, the wood of which answers well for furniture, and produces a fruit having some resemblance to the crab-apple. The fruit seems to possess, in certain stages of its growth, an acrid or deleterious quality; and indeed it was supposed, from the idle tales of credulous travellers, that it is a deadly poison. Even the drops of rain which fell from the leaves were said to have acquired so much acrimony as to corrode the clothes and skin of those on whom they fell; but these stories are altogether without foundation. We have often taken the shelter of a manchineal tree, loaded with fruit, during the torrents of rain of that tropical climate, and never experienced the slightest injury.

Syngenesia.

Cucumis. (1) Cal. five-toothed; cor. five-cleft; filaments three. (2) Cal. five-toothed; cor. five-cleft; style three-cleft.

To this genus belong the Common Cucumber, Cuc. *Sativus;* the small Wild Cucumber of Jamaica, Cuc. *Anguria*, which is employed with other pot-herbs in soups; the Melon, Cuc. *Melo*, of which

Diœcia.

there are several varieties; and Coloquintida, or Bitter Apple, Cuc. *Colocynthis*, a native of Turkey, which is sometimes employed in medicine.

Class XXII. Diœcia.

In this class the flowers which produce stamens, and those which produce pistils and seeds, are on different plants. The characters of the orders are taken, as in the preceding, from the number and connection of the stamens.

Diandria.

Vallisneria. *Gen. char.*—(1) Sheath many-flowered, two-parted; cor. three-parted. (2) Sheath one-flowered; cal. three-parted; cor. three-parted; one pistil; caps. one-celled.

Val. *Spiralis*; a remarkable aquatic plant, which shoots up from the bottom of ditches in Italy, and in still places of the river Rhone. The flowers, bearing stamens, are produced from a distinct root, on short straight stalks; and, as they approach to maturity, are separated from the stalks, suddenly expand when they reach the surface, and float about in great profusion. The fertile flowers are attached to long spiral stalks, which, by uncoiling, permit them to rise to the surface, where the seeds are ripened in the open air. The spiral stem is finely accommodated to the variable depth of the waters in which this curious plant grows.

Salix. *Gen. char.*—(1) Cal. a scale of the catkin; cor. none; gland of the base nectariferous; stamens two, seldom five. (2) Cal. a scale of the catkin; cor. none; stigmas two; caps. superior, one-celled, two-valved; seeds downy.

Sal. *Helix*, Rose Willow; with lance-shaped, pointed, serrated, smooth leaves; style lengthened, thread-shaped, and stigmas linear. In willow and marshy grounds; rarely exceeds ten feet in height, and is much employed in all kinds of basket-work.

Sal. *Triandra*, Long-leaved, or Smooth Willow; with linear, oblong, serrated, smooth leaves, and germens on footstalks. Frequent in willow grounds and on the banks of rivers; rises to the height of thirty feet, and is esteemed one of the most valuable basket willows.

Sal. *Pentandra*, Sweet Willow, or Bay-leaved Willow; with five stamens; elliptical, lance-shaped, notched, smooth leaves, and germens smooth, nearly sessile. On banks of rivers in the north of England and south of Scotland.

Sal. *Vitellina*, Yellow Willow; with lance-shaped, acute, serrated leaves, smooth on the upper surface; serratures cartilaginous; stigmas notched. In willow grounds and marshes.

Sal. *Fragilis*, Crack Willow; with lance-shaped, serrated, very smooth leaves; footstalks toothed, glandular, and nectary in the flowers bearing stamens double. In willow grounds, and on the banks of rivers, and is remarkable for the brittleness of its branches. The bark of this species is sometimes employed as a substitute for Peruvian bark.

Sal. *Alba*, Common White Willow; with lance-shaped, pointed, serrated leaves, downy on both sides, the lowest serratures glandular. In woods and moist meadows, and becomes a tall tree.

Diœcia.

Of this genus forty-three species are described in the *Flora Britannica*. *Salix Babylonica*, Weeping Willow, is cultivated on account of the elegance and beauty of its delicate pendulous branches.

Triandria.

Empetrum. *Gen. char.*—(1) Cal. three-parted; cor. three-petaled; stamens capillary from three to nine. (2) Cal. three-parted; cor. three-petaled; stigmas nine; berry superior, nine-seeded.

Emp. *Nigrum*, Black Crow, or Crake Berry; with trailing stems. Frequent in elevated heaths in the northern parts of Britain.

Ruscus. *Gen. char.*—(1) Cal. six-leaved; cor. none. (2) Cal. six-leaved; cor. none; pistil one; berry superior, three-celled; seeds double.

Rus. *Aculeatus*, Knee-holly, or Butcher's Broom; with dagger-pointed sharp leaves, producing flowers on the upper surface. In woods and heaths in a gravelly soil; abundant at Stoke near Gosport.

Tetrandria.

Viscum. *Gen. char.*—(1) Cal. none; petals four, dilated at the base, united, and in the form of calyx; anthers sessile, attached to the petals. (2) Cal. slightly margined; petals four, dilated at the base; style none; berry inferior, one-seeded.

Vis. *Alumb*, Misseltoe; with lance-shaped, obtuse leaves; divided stem; spikes axillary. This is the celebrated misseltoe, a parasitical plant, which attaches itself to trees, and was held in great veneration by the ancient druids, who employed it in the celebration of their mysterious rites.

Myrica. *Gen. char.*—(1) Cal. scale of catkin concave; cor. none. (2) Scale of the catkin hollow; cor. none; styles two; berry one-seeded.

Myr. *Gale*, Sweet Gale, or Dutch Myrtle; with lance-shaped slightly-serrated leaves, and shrubby stem. Not uncommon in marshy places; grows to the height of two or three feet, and may be readily distinguished by its agreeable fragrance. In Wales and in Scotland it is sometimes employed to keep off vermin from clothes and apartments, to tan calf-skins, and to communicate a yellow colour to wool.

From the berries of Myr. *Cerifera*, Candle-berry Myrtle, a native of North America, candles for domestic use are made.

Trophis. *Gen. char.*—(1) Cal. none; cor. four-petaled. (2) Cal. and cor. none; style two-cleft; berry one-seeded.

Troph. *Americana*, Ramoon Tree. A native of Jamaica; rises to the height of twenty feet; and the leaves and tops of the branches afford a nutritious and desirable food for horses and cattle, and are thus employed in dry seasons when the grass crops are deficient.

Pentandria.

Cannabis. *Gen char.*—(1) Cal. five-parted; no corolla. (2) Cal. one-leaved; cor. none; styles two; seed, a nut.

Can. *Sativa*, Hemp. A native of India, but extensively cultivated in Europe on account of the fibres of the stem, which furnish the hemp of commerce, one of the most important substances in the arts.

Humulus. *Gen. char.*—(1) Cal. five-leaved; cor. none; anthers with a double pore at the summit. (2) Cal. scale of the catkin oblique, entire; cor. none; styles two; seed one, coated.

Hum. *Lupulus*, Hop; grows among brushwood and in hedges, was introduced from Flanders into England about 1520, and is now extensively cultivated on account of its seeds and membranous seed-coverings, which furnish the hops of commerce, the infusion of which, of a bitter aromatic nature, is employed for preserving and communicating an agreeable flavour to malt liquors.

Hexandria.

Myristica. *Gen. char.*—(1) Cal. one-leaved, three-cleft; cor. none. (2) Cal. one-leaved, three-cleft; cor. none; germen oval; fruit a drupe. Three species of this genus have been described; but by far the most important is the Nutmeg Tree, *Myristica Moschata*, which produces the precious and delicate spice, and which is a native of many of the islands in the East Indies; but its cultivation was chiefly confined by the Dutch to the island of Banda, for the purpose of retaining a monopoly of the trade; and, with the same view, all the plants within their power in the other islands were destroyed.

The nutmeg tree grows to the height of thirty feet. When the nutmegs are ripe, the natives ascend the trees and collect them with the hand, by pulling the branches near them with long hooks. The fruit, in this state, is composed of a green shell, or rind, of a fibrous substance of a beautiful red colour, which is the spice called mace, and of the nutmeg itself, which is inclosed within the two coverings. When the first rind is separated, which is done when they are gathered from the tree, the nutmegs are carried home, and the mace is carefully taken off with a small knife. Exposed to the sun for a day, and afterwards placed in an airy situation, the mace loses its bright red colour, is moistened with sea-water to prevent it from drying too much, and is then put into small bags and strongly pressed, when it is ready for the market.

The nuts, which are still covered with a woody shell, are exposed to the sun for some days, afterwards dried before a fire, and then beaten with small sticks to remove the shell, which flies off in pieces. The nutmegs thus prepared are distributed into three parcels, the first of which includes the largest and best formed, which are destined for the European market; the second contains those of an inferior kind, which are reserved for the consumpt of the country; and the third contains those which are unripe and of a small size, which are usually burnt.

Before they are ready for exportation, the nutmegs are subjected to another process; to prevent the depredations of insects, they are immersed two or three times in a mixture of lime and salt-water, afterwards laid in a heap, where they heat, and after having sweated sufficiently they are prepared for a sea voyage.

Octandria.

Populus. *Gen. char.*—(1) Cal. scale of the catkin ragged; cor. turbinated, entire. (2) Cal. scale of the catkin ragged; cor. turbinated, oblique, entire; stigmas four; caps. superior, two-celled, two-valved; seeds downy.

Pop. *Alba*, Great White Poplar; with heart-shaped, roundish, lobed, toothed leaves, hoary underneath; catkins ovate. In moist woods.

Pop. *Tremula*, Trembling Poplar, or Aspen; with roundish toothed leaves, smooth on both sides; footstalks compressed; branches rough. In moist woods, and becomes a tall tree.

Pop. *Nigra*, Black Poplar; with rhomboidal, pointed, serrated leaves, smooth on both sides; a lofty tree, which grows on banks of rivers, and in watery places.

Rhodiola. *Gen. char.*—(1) Cal. four-parted; petals four; nectaries four, notched. (2) Cal. four-parted; petals four; nectaries four, notched; pistils four; caps. four; many-seeded.

Rhod. *Rosea*, Rose-root. On the mountains of Wales and Yorkshire, and frequent on the rocky shores of the Western islands of Scotland; it is easily recognised by its succulent, smooth, azure, imbricated leaves, and yellowish flowers.

Enneandria.

Mercurialis. *Gen. char.*—(1) Cal. three-parted; cor. none; stamens from nine to twelve. (2) Cal. three-parted; cor. none; styles two; caps. two-celled; seeds single.

Merc. *Perennis*, Perennial Dog's Mercury; with very simple stem, rough leaves, and creeping root; perennial; flowers in April and May, and is common among brushwood.

To an inexperienced eye this plant has something of the appearance of spearmint, and has been used by mistake in the form of infusion, with fatal effects to those who swallowed it. It is said also to be equally deleterious to other animals, sheep, for example, as to man.

Merc. *Annua*, Annual Dog's Mercury; with branched stem, smooth leaves, flowers in racemes, and fibrous root; frequent in waste places near towns.

Decandria.

Carica. *Gen. char.*—(1) Cal. scarcely any; cor. five-cleft. (2) Cal. five-toothed; cor. five-petaled; stigmas eight; berry many-seeded.

Car. *Papaya*, Papaw Tree; with leaves peltate-lobed; lobes variously sinuated. Native of Jamaica, and rises with a soft herbaceous stem to the height of eighteen or twenty feet. The fruit of the papaw grows to the size of a small melon; in its green state is employed as a pickle or preserve; when ripe, is eaten like the melon with pepper, sugar, and salt; or boiled, is beaten up like turnips for the table; and the leaves are employed by the negroes for washing clothes.

Monadelphia.

Juniperus. *Gen. char.*—(1) Cal. scales of the catkin; cor. none; stamens three. (2) Cal. scales of the catkin few, become at last fleshy, and unite into a three-seeded berry.

Jun. *Communis,* Common Juniper; with leaves ternate, spreading, needle-shaped, longer than the berry. Common in heaths and elevated places, and well known by the sweetish aromatic berries which it produces.

Taxus. *Gen. char.*—(1) Cal. none; cor. none; stamens numerous; anthers peltate, eight-cleft. (2) Cal. pitcher-shaped, entire; style none; seed one, placed on the berried calyx.

Tax. *Baccata,* Yew Tree; with approximating leaves; grows in mountainous woods, and moist, loamy soils. The remains of an old wood of yew trees in Upper Lorne, in the Western Highlands of Scotland, were observed by Mr Lightfoot; and the trunk of a decayed yew tree in Fortingal church-yard is mentioned by Mr Pennant, in his tour in Scotland, as 56½ feet in circumference. Before the use of fire-arms, when the bow and arrow formed a principal warlike instrument, the yew, it is said, was planted in every church-yard to supply the inhabitants with bows. As an evergreen, and susceptible of pruning into any form, the yew was much employed in the old fashioned style of gardening in this country, for thick lofty hedges. The wood is reddish and veined, hard, and smooth, and much employed in cabinet-making and turnery.

The berries of the yew-tree are generally admitted to be free from any poisonous quality, but the leaves have been supposed to be deleterious to animals; but it seems doubtful whether this charge be not less owing to any noxious property than to its lurid aspect and peculiar situation, which have furnished an impressive image to the author of the "Grave."

> Well do I know thee by thy trusty yew,
> Cheerless, unsocial plant, that loves to dwell
> Midst skulls and coffins, epitaphs and worms;
> Where light-heeled ghosts, and visionary shades,
> Beneath the wan, cold moon, as fame reports,
> Embodied thick, perform their mystic rounds.
> No other merriment, dull tree, is thine.—Blair.

Class XXIII. Polygamia.

In this class the stamens and pistils are separate in some flowers, and they are united in others, either on the same or on two or three distinct plants. This diversity is the foundation of the three orders into which the class is divided. As in the two former classes, the flowers with stamens are marked by the figure (1), and the flowers with pistils by the figure (2). The flowers producing both stamens and pistils are marked (3).

Order I. Monœcia.

Musa. *Gen. char.*—(3) Cal. none; cor. two-petaled; stamens six, one of which is fertile; fruit inferior. (3) Cal none; cor. two-petaled; stamens six, five of which are perfect; pistil one; no berry.

Musa *Paradisaica,* Plantain-tree; with nodding spadix or flower-spike, and flowers producing stamens permanent. This remarkable plant is cultivated in the West Indies on account of its fruit, and rises to the height of 15 or 20 feet, on a round, soft stem, composed of the elongated footstalks of the leaves; which latter are sometimes eight feet in length and two in breadth. The fruit or plantains are about a foot in length, and two or three inches in diameter, when fully grown, and of a pale yellow colour, and luscious sweet taste. A bunch of fruit, from a single plant, sometimes exceeds 40 pounds in weight; but the plantain is generally used as an excellent substitute for bread, before it is ripe and has acquired the sweet taste; and for this purpose, the outer skin being removed, it is either roasted or boiled. Plate 34. Fig. 5.

Musa *Sapientum,* Banana Tree; with the spadix or flower-spike nodding, and flowers producing stamens deciduous. The banana tree nearly resembles the plantain, but the stem is marked with dark purple spots, the fruit is shorter, rounder, and in more compact bunches, and when it is ripe the pulp is of a more agreeable flavour and more delicious taste.

The plantain and banana are supposed to have been brought originally from Guinea to the Canary islands, and from them introduced to the West Indies, where they have been long extensively cultivated. The green leaves are an excellent food for horses or cattle; cordage is made of the fibres of the plant by the natives of the Philippine islands; and encouragement has been given to a similar manufacture by public premiums in Jamaica.

Mimosa. *Gen. char.*—(1) Cal. five-toothed, cor. five-cleft, stamens five, ten, or more. (3) Cal. five-toothed, cor. five-cleft, stamens five or more, pistil one, fruit a pod.

Mim. *Verticillata,* Whorled-leaved Mimosa; unarmed, with linear sharp leaves in whorls. In this species, as in some others from Botany Bay, of which it is a native, the leaves on the seedling plants are pinnated, but afterwards grow in whorls; it is a greenhouse plant, and ripens its seeds in this country.

Many species of this genus are natives of New Holland. Mimosa *Nilotica,* is a native of Egypt and the East, and produces the gum-arabic of commerce; see Plate 34. Fig. 3.: And Mimosa *Pudica,* is a well known plant in the stove, and remarkable for the irritability of its leaves and stems, which shrink and contract with the slightest touch.

Atriplex. *Gen. char.*—(3) Cal. five-parted, inferior; cor. none; stamens five; style two-parted, seed one. (2) Cal. two-leaved; cor. none; style two-parted; seed one, compressed.

At. *Patula,* Spreading Halberd-leaved Orache; with spreading shrubby stem, leaves somewhat square and halberd-shaped. Common in waste and cultivated grounds, and exhibiting some varieties when it grows on the sea-shore.

At. *Angustifolia,* Narrow-leaved Orache; with entire lance-shaped leaves, the lowest somewhat halberd-shaped; common in waste and cultivated places.

In the second order of this class, Diœcia, the different flowers are on two different plants; but excepting *Hippophae,* which is generally arranged under Monœcia Tetrandria, no distinct example has occurred to the extensive experience and acute observation of Dr Smith.

Order III. Triœcia.

Ficus. *Gen. char.*—Common receptacle, turban-shaped, converging, closed, fleshy. (3) Cal. five-parted, cor. none, pistil one, seed one. (1) Cal. three-parted, cor. none, stamens three. The flowers producing stamens and those producing pistils are included within the same common receptacle, but with the partial fructification distinct.

Fic. *Carica,* Fig Tree; with palmated, nearly three-lobed leaves, and pear-shaped, smooth fruit. The figs of commerce are the preserved fruit of this tree, which is extensively cultivated in Turkey, and in the warmer regions of Europe.

Fic. *Indica,* or Banyan Tree, is one of the most remarkable vegetable productions; shoots are thrown out from the horizontal branches, and as they extend towards the earth increase in size, and at last strike into the ground and become stems. New branches push out, which, as they extend, again form roots and new stems, till at last a single tree becomes the parent of an extensive grove, appropriately characterised by the poet as a "pillared shade high overarched." Some banyan trees cover an immense extent of surface. A tree of this description in an island of the river Nerbudda, in India, occupies a space which exceeds 2000 feet in circumference; the chief trunks amount to 350, and the number of smaller stems is more than 3000, although it is considerably reduced by the encroachment of floods on the banks of the island.

Cubbeer Burr, the name of this famous tree, derived from a venerated saint, is celebrated throughout Hindostan for its beauty and magnitude; thousands of votaries, from all parts of the Mogul empire, repair to the sacred spot, at stated seasons, to attend solemn festivals; seven thousand persons, it is said, may repose under its ample shade; and numerous colonies of wood-pigeons, peacocks, and singing birds, with large families of monkeys, find abundant accommodation in its thick, wide-spreading branches, which, in the proper season, offer a copious supply of small scarlet-coloured figs, as food to its crowded inhabitants. The banyan tree may be regarded as a natural temple in eastern regions; it is held sacred by the natives, and idols are set up under its shade, before which they perform their devotions. It is also called the *tree of councils,* from the people assembling under its shade for deliberating on civil affairs. Plate 34. Fig. 4.

Class XXIV. Cryptogamia.

In this class the parts of fructification are so minute that they cannot be arranged according to the principles observed in the preceding classes; but the plants which it includes are considerably different in their structure and habits from the other vegetable tribes; it is divided into five orders.

Order I. Filices, or *Ferns.*

This order is subdivided into three sections, which are characterised by the fructifications being spiked, arranged on the under surface of the leaf or frond, or being near the root.

Equisetum. *Gen. char.*—Catkin with peltated scales including the parts of fructification; small involucrums, two-valved; seeds numerous, naked, infolded by four filaments producing pollen.

Equis. *Palustre,* Marsh Horsetail; with angular branched stems; fructifications on the summit; branches simple, erect, slightly rough. In wet and marshy places.

Equis. *Arvense,* Corn Horsetail; with barren stems, branched all round; branches slightly rough, stems producing seed, simple. Frequent in moist meadows, and among corn in a wet soil.

Equis. *Hyemale,* Rough Horsetail, or Shavegrass; with a naked, very rough stem, slightly branched at the base, and terminal catkin. In marshes and moist woods; and to the habitats noticed in the Flora Britannica may be added, a place where water stood in the winter on the Newton-green near Ayr, and the banks of the Doon, three miles south from the same place. The dried stems are much employed by cabinet-makers for polishing their work.

Ophioglossum. *Gen. char.*—Spike two-rowed, capsules two-valved, sunk, and opening transversely.

Oph. *Vulgatum,* Common Adder's-tongue; with ovate veinless frond; in moist meadows and pastures, but not very common.

Osmunda. *Gen. char.*—Spike branched, capsules two-valved, naked, globular.

Os. *Lunaria,* Common Moonwort; with pinnated frond, and spike rising from the base; the leaflets crescent-shaped, crenated. In dry pastures and meadows.

Os. *Regalis,* Royal Moonwort, or Flowering Fern; with frond twice pinnated, and spike produced at the summit; leaflets heart-shaped, lanceolate, smooth. This splendid plant, when in full vigour, rises to the height of three or four feet, and is not uncommon in marshy places and the crevices of rocks in the Western Highlands of Scotland.

Lycopodium. *Gen. char.*—Capsules axillary, single, two-valved, naked, slightly kidney-shaped, compressed.

Lyc. *Clavatum,* Common Clubmoss; with scattered filamentous leaves; flower-bearing stems, bristly. Not uncommon in elevated heaths, and readily distinguished by its long, trailing, branched stems, and erect flower-stalks, which are sometimes divided into two or three spikes.

Lyc. *Selago*, Fir Clubmoss; with entire lance-shaped scattered leaves, and erect divided stem. In moist places on mountainous heaths.

Polypodium. *Gen. char.*—Fructifications in roundish points; scattered; not marginal; no involucrum.

Pol. *Vulgare*, Common Polypody; with pinnatifid frond, lobes oblong, somewhat serrated, obtuse; root scaly. Common on walls and on the trunks of trees.

Pol. *Phegopteris*, Pale Mountain Polypody; with pinnated frond; leaflets lance-shaped, pointed, pinnatifid, united at the base, the lowest reflected. In fissures of rocks and moist places, in elevated situations, but not very common. Plate 35. Fig. 7.

Aspidium. *Gen. char.*—Fructifications in roundish points, scattered, not marginal, involucrum umbilicated, opening almost on all sides.

Asp. *Filix Mas*. Male Fern; with doubly pinnated frond; leaflets, obtuse, serrated, with chaffy footstalk; involucrum bent inwards. Common in woods and shady places.

Asp. *Aculeatum*, Common Prickly Shield Fern; with doubly pinnated frond, leaflets ovate, crescent-shaped, ciliated, spinous, hairy underneath. In moist rocky places and woods. Plate 35. Fig. 8.

Blechnum. *Gen. char.*—Fructifications in continuous longitudinal lines near the rib; involucrum superficial, continuous, opening towards the rib.

Blech. *Boreale*, Rough Spleenwort; with smooth pinnated frond; leaflets linear, bluntish, entire, nearly equal at the base. Common in woods and heaths. Plate 35. Fig. 5. Osmunda *spicant* of Lightfoot and others.

Scolopendrium. *Gen. char.*—Fructifications in double scattered lines, involucrum superficial, opening longitudinally.

Scol. *Vulgare*, Common Hart's-tongue; with simple lance-shaped frond, smooth underneath. Common in moist, rocky, and shady places. Plate 35. Fig. 6. *Asplenium Scolopendrium*, Spec. Plant. of Lightfoot and other botanists.

Asplenium. *Gen. char.*—Fructifications in scattered lines; involucrum opening towards the rib.

Asplen. *Marinum*, Sea Spleenwort; with pinnated frond, leaflets ovate, oblique, serrated, obtuse, unequal at the base, and wedge-shaped. Rocks near the sea in Britain.

Asplen. *Septentrionale*, Forked Spleenwort; with pinnated, three-cleft frond, leaflets alternate, linear, ragged at the summit. In the fissures of rocks; Arthurs' Seat, Edinburgh. *Acrostichum Septentrionale* of Lightfoot, Withering, and others.

Asplen. *Palmatum*, Palmated Spleenwort; with five-lobed, heart-shaped frond; three intermediate lobes pointed. Native of Spain, Portugal, and the Canary Islands. Plate 35. Fig. 1.

Lonchitis. *Gen. char.*—Fructifications in lines under the sinuses of the frond.

Lon. *Hirsuta*, Hairy Spleenwort; with blunt entire pinnatifid fronds; native of the mountains of Jamaica, and grows to the height of four or five feet.

Lon. *Pedata*, Footed Spleenwort; with fronds pedate, leaflets pinnatifid and slightly serrated. Native of the mountains of New Liguanea, in Jamaica; grows two or three feet in height on a single stalk; divides into three parts, of which the middle is a single frond, and the lateral divisions are composed of three fronds each. Plate 35. Fig. 2. a single frond, and Fig. 3. the entire plant.

Adiantum. *Gen. char.*—Fructifications in roundish, distinct, marginal points.

Ad. *Capillus Veneris*, True Maiden-hair; with the frond alternately decompounded; leaflets wedge-shaped, lobed, on footstalks. On rocks and moist walls near the sea.

Lindsæa; fructifications linear, continued, submarginal; capsules opening interiorly.

Lind. *Reniformis*, Kidney-shaped Lindsæa; with simple, kidney-formed, very obtuse frond. Native of Guiana. *Lin. Trans.* Vol. III. See Plate 35. Fig. 4.

Pteris. *Gen. char.*—Fructifications in a continued marginal line; involucrum from the inflected margin of the frond, continuous, opening interiorly.

Pter. *Aquilina*, Common Brakes; with supra-decompound frond, leaflets lance-shaped, somewhat acute; the lowest pinnatifid, the upper smaller. In heaths and neglected pastures, very common.

Order II. Musci, *Mosses*.

The plants arranged under this order are furnished with distinct leaves, and often with a distinct stem. The membranous corolla, which is of a conical form, is called a *calyptra*, or veil, and the summit is the stigma. This veil covers the capsule, which, before the seed ripens, is raised on a footstalk. The capsule, which opens by a vertical lid, consists of one cell and one valve, and the seeds are extremely minute and numerous. The stamens and pistils of the mosses are generally in separate plants, but in a few species they are united in the same flower.

According to the method adopted by Linnæus, the genera of mosses are determined chiefly by the lateral or terminal situation of the capsule; but the structure of the fringe or *peristomium*, which borders the orifice of the capsule, as proposed by Hedwig, affords more obvious and more precise marks of discrimination. The fringe is either simple or double, and is composed either of separate teeth, as is mostly the case, with the external fringe, or of a plaited and jagged membrane, which is the form of the inner fringe when it exists. The number of teeth, which is remarkably constant in each genus and species, is either four, eight, sixteen, thirty-two, or sixty-four.

The elegance and beauty which are exhibited in the form and structure of this singular tribe of plants, cannot fail to excite admiration, and amply reward curiosity for the care and industry requisite in studying them;—they are spread over the surface of the earth, are found in tropical climes, as well as in polar regions, and offer themselves for examination at all seasons; for even the severity of winter, which overwhelms the gayer beauties of the empire of Flora with desolation, and leaves behind a dreary waste, is not unfavourable to their growth and vigour.

The mosses are divided into three sections; as they are destitute of fringe, or as they are furnished with a single or double fringe. Of these sections the following are examples.

Sect. I. *With no Fringe.*

Sphagnum. *Gen. char.*—Capsule with a naked mouth; calyptra divided horizontally, surrounding the capsule at the base; anthers surrounded with a ring.

Sphag. *Latifolium*, Broad-leaved Bog Moss; with swelled deflected branches, and ovate, obtuse, inflated leaves; very common in marshy bogs.

Sphag. *Capillifolium*, Slender Bog Moss; with thread-shaped, deflected branches, and ovate-lance-shaped, plain, pointed, closely imbricated leaves; in moist places on elevated heaths.

The two species now described are synonymous with Sphagnum *Palustre*, of the Species Plantarum, Withering, and others.

Phascum. *Gen. char.*—Capsule ovate, closed, deciduous, with the operculum not opening.

Phas. *Subulatum*, Awl-leaved Earth Moss; with capsule nearly sessile, and leaves awl-shaped, spreading, dilated at the base, very slender at the summit; on heaths and sandy banks.

Phas. *Muticum*, Common Dwarf Earth Moss; with ovate, awnless, concave, closing leaves, and sessile globular capsule; frequent on banks and in hedges.

Phas. *Cuspidatum*, Sharp-leaved Dwarf Earth Moss; with ovate, bearded, pointed leaves; upper leaves closing, and capsule broadly elliptical, nearly sessile. In heaths, banks, and walks, especially in a sandy soil, abundant.

Gymnostomum. *Gen. char.*—Capsule with a naked mouth, and deciduous lip; entire calyptra separating from the base.

Gymnost. *Truncatulum*, Little Blunt-footed Beardless Moss; with ovate, pointed, plain, entire leaves, and turban-shaped truncated capsule. In flowers, banks, and by the sides of ditches.

Gymnost. *Ovatum*, Hairy-leaved Beardless Moss; with ovate, obtuse, very entire, concave, awned leaves, and ovate capsule; on banks and mud walls.

Gymnost. *Pyriforme*, Pointed Pear-shaped Beardless Moss; with very simple and very short stem; leaves ovate, acute, slightly toothed; capsule obovate, and lid bluntly dagger-shaped. On banks and wet heaths.

Sect. II. *With a Simple Fringe.*

Splachnum. *Gen. char.*—Capsule cylindrical, set upon a fleshy process; fringe simple, with sixteen teeth approaching by pairs.

Splach. *Mnioides*, Green Tapering Gland Moss; with the process obconical, green, and leaves elliptical, lance-shaped, entire, awned; in moist places of elevated districts.

Splach. *Ampullaceum*, Purple Gland Moss; with greenish, purple, obconical, blunt process, three times thicker than the capsule; leaves lance-shaped, acute, serrated. In marshy bogs and moist heaths.

Tetraphis. *Gen. char.*—Capsule oblong; fringe with four pyramidal, erect, loose teeth.

Tet. *Pellucida*, Transparent Four-toothed Moss; *Mnium Pellucidum*, Spec. Plant. In moist, shady places, and at the roots of trees.

Encalypta. *Gen. char.*—Capsule cylindrical; fringe with sixteen linear, upright teeth; calyptra bell-shaped, inflated, loose.

Enc. *Vulgaris*, Common Extinguisher Moss; with calyptra, having a very entire, smooth margin; stem nearly simple, and leaves lanceolate. In the fissures of rocks, on walls, and shady banks.

Enc. *Ciliata*, Greater Extinguisher Moss; with calyptra toothed on the margin; stem branched, and leaves lanceolate. On elevated rocks.

The two last species are varieties of *Bryum Extinctorium*. Spec. Plant.

Trichostomum. *Gen. char.*—Capsule oblong; fringe with thirty-two thread-shaped, somewhat upright teeth, joined in pairs, or connected at the base.

Trich. *Trifarium*, Three-ranked Fringe Moss; with leaves awl-shaped, keeled, entire, in three rows; capsule ovate, and stem branched. In barren places on mountains.

Trich. *Capillaceum*, Capillary Fringe Moss; with slender sheathing leaves in two rows, conical lid, and stems forming a close turf. In elevated marshes, as on the Pentland hills near Edinburgh.

Tortula. *Gen. char.*—Caps. oblong, with numerous thread-shaped teeth, spirally convoluted, and with many folds.

Tort. *Rigida*, Rigid Screw Moss; with very short stem; spreading, stiff, blunt leaves, rolled inwards, and without nerves; caps. cylindrical and lid conical. On rocks, banks, and walls. *Bryum Rigidum* of Withering, Hudson, and others.

Tort. *Ruralis*, Great Hairy Screw Moss; with branched stem; leaves blunt, recurved, hairy at the summit; upper leaves star-shaped; capsule ovate, cylindrical. Common on walls, cottages, and trunks of trees. *Bryum Rurale* of Spec. Plant. Withering, and others.

Tort. *Subulata*, Awl-shaped Screw Moss; with short, somewhat simple stem; leaves ovate, lance-shaped, pointed; caps. cylindrical, and lid awl-shaped, upright. Common in moist, shady places, but rare in the northern districts of Britain. *Bryum Subulatum* of Spec. Plant. Hudson, Withering, Lightfoot, &c.

Tort. *Muralis*, Wall Screw Moss; with very short, nearly simple stem; leaves ovate, sharp, hairy; caps. elliptic, cylindrical, and lid conical. One of the most common mosses; on walls and houses. *Bryum Murale*, Spec. Plant.

Sect. III. *With Double Fringe.*

Orthotrichum. *Gen. char.*—Caps. oblong, terminal; external fringe, with sixteen teeth; internal, with eight or sixteen thread-shaped, and sometimes none; calyptra often rough, with straight hairs, angular.

Orthot. *Striatum,* Common Bristle Moss; with branched stem; leaves lance-shaped, keeled, bent back, spreading; calyptra entire, and internal fringe with sixteen teeth. On the trunks of trees. *Bryum Striatum* of Spec. Plant. and Withering, and *Polytrichum Striatum* of Hudson and Hull.

Orthot. *Crispum,* Curled Bristle Moss; with branched stem; with linear leaves bent back and waved by drying, and footstalks lengthened and thickened at the summits. On trees. *Bryum Striatum,* Spec. Plant; *Bryum Crispum,* Withering.

Neckera. *Gen. char.*—Caps. oblong, proceeding from a lateral *perichætium* or sheath; external fringe, with sixteen sharp teeth; internal, with sixteen thread-shaped intermediate teeth; calyptra smooth.

Neck. *Pumila,* Small Feathery Neckera; with pinnated branches; leaves in two rows, ovate, slightly waved, and footstalk scarcely exceeding the sheath. On the trunks of trees, but rare. *Hypnum Pennatum* of Withering, and *Fontinalis Pennata* of Hudson.

Neck. *Crispa,* Crisped Neckera; with pinnated branches, leaves oblong, transversely wrinkled, and in two rows, and footstalk double the length of the sheath. On chalk-hills and elevated woods in a dry soil. *Hypnum Crispum,* Spec. plant. Hudson, Withering, Lightfoot.

Neck. *Heteromalla,* Lateral Neckera; with diffuse branched stem, leaves ovate, sharp, concave, imbricated on all sides, and capsule sessile, on one side. On the trunks of trees.

Mnium. *Gen. char.*—Caps. cylindrical, furrowed; external fringe, with sixteen teeth dilated at the base; internal, membranaceous, divided into segments; calyptra smooth, footstalk terminal.

Mnium *Androgynum,* Narrow-leaved Spring Moss; monœcious, caps. erect, lid conical; leaves imbricated, spreading, and toothed at the summit. In moist shady places.

Mnium *Palustre,* Greater-forked Spring Moss; diœcious caps. oblique, lid conical, leaves sharp. In marshy and flooded places.

Funaria. *Gen. char.*—Caps. obovate, external fringe, with sixteen teeth, oblique, uniting at the summit internal, with sixteen plain teeth; flowers terminal, calyptra square.

Fun. *Hygrometrica,* Twisting Cord Moss; with concave leaves and ventricose capsule. Common in moist, sandy heaths, gardens, and neglected walks. *Mnium Hygrometricum,* Spec. Plant. Withering, Lightfoot. The flower-stems twist round when moistened, or even breathed upon.

Bartramia. *Gen. char.*---Caps. round, furrowed; external fringe with sixteen teeth, dilated at the base; internal, membranaceous, folded, divided into various segments; calyptra smooth; lid depressed.

Bart. *Pomiforme,* Apple Bartramia; with footstalks erect, exceeding the stem; leaves awl-shaped, one-nerved. In shady places and crevices of rocks. *Bryum Pomiforme.* Spec. Plant.

Bart. *Fontana,* Fountain Bartramia; with erect footstalks exceeding the stem, entire ovate leaves, erect, thread-shaped, fasciculated branches. Abundant on the banks of rivers and in marshy places. *Mnium Fontanum,* Spec. Plant. Withering and Lightfoot.

Polytrichum. *Gen. char.*---External fringe, with thirty-two or sixty-four short inflected teeth; internal fringe, a plain undivided membrane; calyptra often double, the external one hairy.

Polyt. *Commune,* Hair-moss; with simple stem; leaves linear, lance-shaped, slightly serrated; caps. erect, square; external fringe, with sixty-four teeth; calyptra double. Common in moist woods and boggy places.

Polyt. *Undulatum,* Waved Hair Moss; with lance-shaped serrated leaves that curl in drying; cylindrical nodding capsule, and calyptra rough on the summit; teeth of the fringe thirty-two. Frequent in shady places and hedges.

Order III. Hepaticæ, *Liverworts.*

The plants included under this order are separated from the Algæ or Flags, under which they were arranged by Linnæus. In the Liverworts the herbage is commonly frondose; the fructification originates from what is at the same time both leaf and stem; and the capsules have no lid or operculum.

Jungermannia. *Gen. char.*—(1) On a footstalk and naked, anther four-valved. (2) Sessile naked, with roundish seeds.

Jung. *Trichomanes,* Powder-headed Jungermannia; with fronds simply pinnated; leaves ovate, plain, very entire; stem with the pistil at the summit. Near springs and rivulets in moist woods.

Jung. *Asplenoides,* Spleenwort Jungermannia; with fronds simply pinnated, leaflets ovate, slightly ciliated. In moist woods, at the roots of trees, and is said to be the largest of the British species.

Jung. *Complanata,* Flat Pale Green Jungermannia; with creeping shoots; leaflets eared below, and doubly imbricated; branches equal. Common on trunks of trees.

Jung. *Tamarisci,* Red Tamarisk Jungermannia; with leaves imbricated in a double series, upper leaves roundish, convex, obtuse, one-fourth larger. On trunks of trees, rocks, and in dry stony places; on the rocks of Edinburgh Castle.

Marchantia. *Gen. char.*—(1) Cal. shield-formed, covered underneath with one-leaved corollas; anthers much divided. (2) Cal. sessile, bell-shaped; many-seeded.

March. *Polymorpha,* Great Star-headed Marchantia; with the common calyx ten-cleft; by the sides of wells, and on moist rocks on the banks of rivulets.

A variety of this plant, which some have considered a different species, is smaller in all its parts, excepting the umbellated heads; it grows on walls, rocks, and neglected shady garden-walks.

March. *Hemisphærica,* Hemispheric Marchantia; with the common calyx five-cleft, hemispherical, and destitute of sheath. On wet banks, by the sides of rivers, not uncommon; in the King's park at Edinburgh. The leaves are slightly notched on the margin;

and the margin and under-surface are of a dark red or claret colour, covered with white downy radicles.

Order IV. Algæ, *Flags.*

In this order the herbage is frondose, sometimes of a leathery gelatinous consistence, and sometimes only a crust; and the seeds are produced either in a peculiar receptacle or in the frond itself.

Lichen. *Gen. char.*—(1) Receptacle roundish, somewhat plain, shining. (2) Dust scattered on the leaves.

Lich. *Scriptus*, Lettered Lichen; warty, whitish, with small black branched lines resembling letters. On the smooth bark of trees.

Lich. *Geographicus*, Map Lichen; warty, yellowish, with black lines resembling a map; frequent on rocks, as in the King's Park at Edinburgh.

Lich. *Islandicus*, Eatable Iceland Lichen; leafy, laciniated, with elevated fringed margins. On mountainous places in the Highlands and Lowlands of Scotland; on the Pentland hills near Edinburgh. This lichen contains a considerable proportion of mucilage, and has on that account been recommended as a cure, or as a mild nourishing aliment, in affections of the lungs. The inhabitants of Iceland grind it to powder, and use it as common food, by boiling it either in milk or water, or making it into bread.

Lich. *Rangiferinus*, Rein-Deer Lichen; shrubby, and very much branched. Common in woods and heaths. This plant is the chief support of the rein-deer, an animal of the utmost importance to a large proportion of the inhabitants of the polar regions.

Fucus. *Gen. char.*—(1) Vesicles interwoven with hairs. (2) Vesicles strewed with imbedded grains, slightly prominent at the summit; seeds solitary.

Fucus *Serratus*, Sea-wrack; with frond, plain, divided, ribbed, serrated, toothed, and tubercular terminal fructifications. On sea rocks at low water mark. The leaf is flat, radical, and about two feet long.

Fucus *Vesiculosus*, Common Sea-wrack, or Seaware, in Scotland; grows abundantly on rocks at low water mark, and is collected on the shores of Scotland for making kelp. Several other species of fucus are employed for the same purpose.

Fucus *Palmatus*, Palmated, or Sweet Fucus; dulse, or dilse, in Scotland; with a plain, hand-shaped frond. Common on sea-rocks, and frequently eaten by the inhabitants.

Fucus *Ruscifolius*; found on the southern shores of England; is represented on Plate 35. Fig. 9. Fucus *Menziesii*; a native of the western coast of North America, Fig. 10. Fucus *Sanguineus*, Dock-leaved Fucus; not uncommon on the shores of Britain; is a very elegant species, of a bright red or purple colour, Fig. 11. Fucus *Ilicifolius*, a native of the straits of Sunda, Fig. 12. Fucus *Fraxinifolius*, a native of the East Indies, Fig. 13. See *Historia Fucorum* by Turner.

Order V. Fungi, *or Mushrooms.*

The vegetable nature of this order of plants was long doubted by some naturalists, who were disposed to ascribe to them an animal origin; but the labours of Dryander, Schæffer, and Hedwig, have shewn that they possess a vegetable character, by detecting their seeds, and explaining the parts of fructification. In the *Synopsis Methodica Fungorum* of Persoon, the order of mushrooms is divided into such as produce their seeds internally, or in vessels, and such as have them exposed or imbedded in an appropriate membrane. To the first division belong *Sphæria* and *Lycoperdon*, or Puff-ball; and to the second *Helvella*, in which the seed membrane is smooth and even; *Boletus*, in which it is porous; and *Agaricus*, in which it is composed of parallel plates, denominated *Lamellæ*, or Gills.

Agaricus. *Gen. char.*---Fungus horizontal, lamellated underneath.

Ag. *Chantarellus*, Yellow Agaric, or Chantarelle, Paddock-stool in Scotland; with a stipe or footstalk, and branched lamellæ or gills. Frequent in woods. This species is of a yellow colour; the pileus, when young, is orbicular; when full grown the rim becomes waved and variously lobed; and the gills are branched, curled, and run down part of the stem.

Ag. *Integer*, Equal-gilled Agaric; furnished with a stem; all the gills of the same size. Not uncommon in woods.

Ag. *Piperatus*, Pepper Agaric; with a footstalk pileus plain, lactescent, margin deflected, gills pale, flesh-coloured. Frequent in woods. This mushroom is of a very acrid nature, yet, after being pickled with salt, is eaten by the Russians.

Ag. *Campestris*, Common Mushroom, or Champignon; with a footstalk; white, convex, scaly pileus, and reddish gills. Common in dry pastures after rains. This is the only mushroom which may be eaten with safety; and the juice, preserved with salt and spice, forms the sauce well known by the name of ketchup. The stalk of this mushroom is short, white, solid, and about the thickness of the finger; the pileus, when young, is white, hemispherical, fleshy, and covered with ragged scales; the rim is inflected, and the gills are rose or pink-coloured, and nearly of equal length.

Lycoperdon. *Gen. char.*---Fungus roundish, filled with mealy seeds.

Lyc. *Tuber*, Truffles, or Subterraneous Puff-balls; globular, solid, with sharp tubercles, and without root. Found in woods. This fungus is produced in clusters, three or four inches under ground. The truffles of this country rarely exceed three or four ounces in weight; but in Italy they acquire the enormous size of eight or ten pounds. They are eaten at table either fresh and roasted like potatoes, or dried and sliced as a seasoning to ragouts. Dogs are taught to discover them by the scent.

Lyc. *Bovista*, Common Puff-ball; roundish, opening irregularly. Common in meadows and pastures in the autumn. This species varies much in size, figure, and colour; it has been sometimes found in England as large as a man's head, and specimens have been gathered in Italy of the extraordinary weight of 25 lbs. and two yards in circumference.

APPENDIX.

Palms.

The natural order of palms exhibits such striking peculiarities in the structure and habits of the plants which it comprehends, as to be properly enough reserved for an appendix to the system, as was originally done by Linnæus, in consequence of the limited knowledge which he possessed of these remarkable vegetable productions. From the observations of succeeding botanists, it appears that palms have for the most part six stamens, more rarely three or nine, with three or six petals, and one or three styles. The stamens and pistils are sometimes in the same flower; sometimes in separate flowers on the same plant; and sometimes on different plants,—thus forming monœcious or diœcious plants. The fruit of the palms is generally a drupe. Having some affinity in structure to the liliaceous tribe, which were called by Linnæus the nobles, the palms, from their lofty stature and elegant form, have received the dignified appellation of the princes of the vegetable kingdom.

The genera of palms, which do not exceed ten or twelve, have been divided into three sections, the characters of which are taken from the form of the leaves. In the first they are fan-shaped; in the second pinnated, or wing-shaped; and in the third doubly pinnated.

Chamærops. *Gen. char.*—Diœcious; pericarp three globular one-celled drupes.

Cham. *Humilis*, Smaller Palmeto, or Fan-palm; with large fan-shaped leaves and smooth stems. A common plant in Jamaica, the leaves of which are much employed for thatching cottages; and the berries, which are sweet, are greedily devoured by birds. This species of palm is also a native of Europe; it grows as far north as the vicinity of Nice. Plate 36. Fig. 6.

Thrinax. *Gen. char.*—Perianth minute, six-toothed; stamens six; pericarp a naked berry, one-celled.

Thrin. *Parviflora*, Small-flowered Palmeto Royal, or Thatch-tree; with palmate plaited leaves. Native of Jamaica, and grows abundantly on rocky hills and low moist plains near the sea. It shoots up with a simple stem from ten to twenty feet in height. The leaves are used for thatch, and the trunk is employed for buildings in the sea, for which purpose it is well calculated from its durable quality.

Borassus. *Gen. char.*—Diœcious; (1) cal. a compound sheath; cor. with three oval and concave petals. (2) Cal. a sheath; cor. with three roundish petals; drupe or berry roundish, obtuse, with three seeds.

Boras. *Flabelliformis*, Fan-leaved Palm; with hand-shaped leaves, folded, wide at top, and drawn to a point below; footstalk serrated. This palm is a native of India, rises to the height of thirty feet, and is terminated with a bunch of fan-shaped leaves. The wood, which is hard and durable, is employed in building, and in the construction of domestic implements; the liquid which flows from the wounded tree affords, by evaporation, saccharine matter, and a spirit when it is fermented and distilled; screens and parasols are made of the entire leaves; and, divided into slips, they are converted into mats of various kinds; or, cut into small pieces, are used as a substitute for writing paper.

Corypha, or Mountain Palm, is also diœcious, with a drupe containing one seed; and it includes two species, which are natives of the East Indies and Carolina.

Phœnix. *Gen. char.*—(1) Cal. a three-parted one-valved sheath; cor. with three concave oval petals. (2) Cal. the same; cor. with three petals; fruit oval, one-seeded.

Phœn. *Dactylifera*, Date Tree; with pinnated leaves, leaflets sword-shaped, folded. To the inhabitants of many extensive regions of Asia and Africa, the date tree is the most important vegetable production; it grows with a straight cylindrical stem to the height of thirty or forty feet, thickly set on the upper part with scales, which are the vestiges of old leaves, and is terminated by a bunch of leaves nine or ten feet in length. The fruit is composed of a fine soft pulp, of a sweet and slightly vinous taste, and of a very wholesome and nutritious quality.

The date-tree is a native of the sandy districts of India, Arabia, and the northern regions of Africa; it grows also in the southern parts of Spain, in some of the islands of the Mediterranean, and in some places of France near the sea, although the fruit is rarely ripened; but in Arabia, and in those parts of Africa to the eastward of mount Atlas, countries which produce little corn, this valuable tree fortunately thrives most vigorously, and yields the best fruit. On the borders of the great desert which approaches to mount Atlas, the date-tree, as it supplies the deficiency of corn, and furnishes nearly the whole of the subsistence of the inhabitants, is cultivated with great care. The date-trees are planted at the distance of twelve feet from each other, in the vicinity of streams and rivulets, for the conveniency of supplying them with water, which is necessary at all seasons, but especially during the great heats of summer.

When the date-palm is raised from seed, it seldom produces fruit before it is twelve or fifteen years old. To obviate this inconveniency, the Arabs generally prefer the mode of propagation by shoots selected from the best and most flourishing trees. These shoots, with proper management, begin to bear fruit in three or four years, although it is not till the plant has reached its fifteenth or twentieth year that the fruit is in its highest degree of perfection, after which it is said that it continues to flourish vigorously for 200 or 300 years. The date crop is gathered about the end of November, and the bunches are hung up to dry in an airy situation. A very extensive trade in dates is carried on with the interior districts of Africa, and great quantities are exported to different parts of Europe. Plate 36. Fig. 3.

Elæis. *Gen. char.*—Diœcious, cal. and cor. six-cleft, fruit a drupe, three-valved, one-celled, and one-seeded.

El. *Guineensis*, Palm-oil Tree; with pinnated leaves, and footstalks, furnished on the edges with awl-shaped spines, some of which are hooked, some straight, and the lowest spreading and longest. This palm is a native of Guinea; the seeds being boiled in water yield the palm-oil, a valuable commercial commodity; and from the fermented liquid obtained by tapping the tree, palm wine is made.

Areca. *Gen. char.*—(1) Cal. two-valved, cor. with three sharp-pointed petals. (2) Cal. and cor. in the same sheath, fruit a roundish drupe, with a thick fibrous rind inclosing an oval nut.

Ar. *Oleracea*, Mountain Cabbage-tree; with leaflets quite entire. This tree, which is one of the most stately and most beautiful of the palm tribe, is a native of the West Indies, and common in many parts of Jamaica, where it grows to the height of 100 and of 150 feet. Near the ground it is often seven feet in circumference, and tapering as it ascends; the ash-coloured bark is changed into a deep sea-green at 20 or 30 feet from the top; and it is terminated by pinnated leaves, some of which are 20 feet long, with leaflets often three feet long. When the green bark immediately under the branches is removed, what is called the cabbage is discovered, in thin, snow-white, brittle flakes, which has been compared to the taste of an almond, but with greater sweetness. This part is eaten as cabbage is used in this country, and is considered what it really is—a delicious dish; but to obtain a single dish, a whole tree, or several trees, must be destroyed. Plate 36. Fig. 5.

Ar. *Catechu*, Betel-nut Tree; with pinnated leaves, leaflets opposite, bent back, and bitten off. This palm is a native of India, grows to a great height, and is terminated with six or eight pinnated leaves, each of which is about six feet long. The betel-nut forms an important object of trade in the east; it is employed as a luxury similar to that of tobacco in Europe, and for this purpose it is prepared by mixing it with the leaf of a species of pepper, which, from this use, has obtained the name of betel-leaf. The nut is cut in slices, sprinkled with slaked lime, and wrapped up in the pepper leaves. Other spices and aromatic drugs are employed in the preparation in some parts of India; and the chewing of betel is a very general practice throughout the east.

The wood of both species of Areca, which is hard and durable, is of great use to the inhabitants, as rafters for houses, pales for fences, and water-pipes and gutters.

Cocos. *Gen. char.*—Monœcious: (1) Cal. with three leaves, cor. with three petals. (2) Cal. with two leaves, and cor. with six petals; seed vessel a drupe, with a fibrous husk, including a large oval nut.

Cocos *Nucifera*, Cocoa-nut Tree; is a native of almost every tropical region; grows to the height of fifty or sixty feet, and is terminated by a bunch of ten or twelve leaves, from ten to fifteen feet long. The cocoa-nut tree is of slow growth, but when it reaches maturity it lives long, and produces fruit three or four times a year. By wounding the upper part of the tree, which is green and tender, a sweet thick liquor distils, of an agreeable flavour, and known in Ceylon by the name of tody, is a wholesome and cooling drink while fresh, and acquires, by fermentation, an intoxicating quality. Of the cocoa-nut tree it has been said, that it furnishes meat, drink, medicine, clothing, lodging, and fuel. The kernel of the nut is eaten; the milk is a cooling and pleasant beverage, which is sometimes employed as an emulsion in fevers; a fibrous substance at the base of the branch is converted into coarse cloth; the fibrous covering of the nut is manufactured into strong and durable cordage; the leaves are used as thatch, or made into mats for baskets; the woody part is applied to the purpose of lathing, and the polished shells are made into drinking cups. Plate 36. Fig 4.

Cocos *Guineensis*, Prickly Pole; with the whole plant covered with bristle-shaped spines; fronds distant, and root creeping. Native of the inland woods of Jamaica; rises to the height of forty feet; and thirty or forty trees grow together. This palm is remarkable for being thickly set with a vast profusion of long, sharp, tough spines, with which it is said the Indians arm their arrows.

Cocos *Aculeata*, Prickly Macaw Tree; with spindle-shape trunk, covered with spines. Native of Jamaica, and so called from a bird which feeds upon the fruit. The trunk of this palm is said to be as thick as the human body, grows thirty feet high, and is closely set with sharp black prickles, arranged in circles, and of various lengths.

Ceroxylon *Andicola*, Wax-palm; with simple stem, pinnated leaves, and paniculated spadix or flower-spike. This palm, which is described by Bonpland in his splendid botanical work, seems to be the loftiest vegetable production on the globe; it rises to the height of 200 feet, and is a remarkable exception to the tribe of palms, which are natives of warmer regions; for although it rears its majestic head on the mountain Quindiu, in north latitude 4° 35′, it grows at an elevation of nearly 6000 feet above the level of the sea, and is confined to a space of fifteen or twenty leagues. A peculiar matter, which, by chemical analysis, is found to be composed of two-thirds resin and one-third of a substance resembling wax, exudes from the trunk of the tree, and being collected by the inhabitants, is melted with tallow, and made into candles. From this production the generic name is derived; and the specific appellation is descriptive of its native station on the Andes.

Cycas. *Gen. char.*—(1) An imbricated catkin; cal. a sheathing scale; corolla none; anthers globular, attached to the scale, sessile. (2) Spadix or flower-spike compressed, double-edged; no calyx or corolla; style one; drupe, one-seeded.

Two species of this genus, *Circinalis* and *Revoluta*, both with pinnated leaves, are natives of India, Japan, and China, and afford the nutritious substance known in the shops under the name of Sago; but it appears that the production of sago is not confined to these species of palm, for it is obtained from others, and perhaps might be extracted from the whole of this singular tribe of plants.

The sago is the medullary part, or pith of the plant, which is formed into a paste with water, and

Palms.

when it begins to dry is granulated by passing it through a perforated plate; it is then dried, and appears in the form of roundish grains like seeds, for which it is taken by those who are unacquainted with the origin of this useful substance. Plate 36. Fig. 7.

Observation.—Six species only of the order of palms have been observed in New Holland; and, with the exception of one species in 34° south latitude, all within the tropic. No species were seen on any part of the south coast. Sir Jos. Banks discovered a species of Areca in New Zealand in 38° south latitude; which, it is probable, is nearly the limit of this tribe of plants in the southern hemisphere. In North America they have not been seen beyond 36° of latitude; but in Europe, *Chamærops Humilis* is a native of the vicinity of Nice. No species of palm has yet been discovered in Southern Africa or on the west coast of New Holland, even within the tropic.

Preparation of a Herbarium or Hortus Siccus.

Herbarium.

In prosecuting the knowledge of botany, it is recommended to the student, after being familiar with the terms and definitions, to compare, with the descriptions, those plants, the names of which he is acquainted with, or has an opportunity of learning from others. This preliminary exercise, as it may be called, will greatly abridge his labours, and enable him with more certainty and facility to refer to the class, order, genus, and species, such plants as are new or unknown to him. In botanical excursions a greater number of objects present themselves than can be conveniently examined on the spot; but by collecting plants in their own native soil and situation, many facts relative to their natural history are discovered; and for the purpose of subjecting them at leisure to future investigation, they are put up carefully in a close tin box, that those parts on which the characters depend may remain fresh and entire. The zeal of the enthusiast in botany is not to be limited by times or seasons; he will not fail to grasp at the objects of his pursuit when they are in his power; but when it is equally convenient, plants intended to be preserved are best collected in dry weather; and, when it can be accomplished, specimens in flower and in seed ought to be selected, that all the characteristic parts may be seen.

Plants are preserved by drying them slowly between the leaves of unsized porous paper, by the application of a hot smoothing iron, or in a box of sand. In the first case, the plants being spread carefully between the leaves of the paper, and retaining as much as possible their natural appearance, they are subjected to pressure, which at first should be moderate and afterwards gradually increased as the plants diminish in bulk by the absorption of the moisture. The pressure is applied either by means of a press constructed for the purpose, of two strong boards, of sufficient length and breadth to cover a large sheet of paper, and furnished at the corners with screws, or what answers equally well, a folio book placed upon the paper on a flat board or table, and loaded with other books. In preserving plants in this manner, when much nicety is required, every precaution should be observed not to wound or injure any of their parts by which a copious flow of the juices is produced. If a large quantity of paper be employed, the plants often dry perfectly without being shifted, but when they are crowded together in the same paper it is necessary to change their place, and at the same time to dry the paper daily.

The application of a hot smoothing iron answers, in some cases, sufficiently well, particularly for drying succulent or juicy plants; but it ought to be applied slowly and cautiously, and with a considerable quantity of paper.

The colour of some plants is retained in higher perfection by drying them in a box of sand. After the specimen has been pressed for ten or twelve hours according to the former method, it is placed within a sheet of blossom paper, and laid in the box on a layer, an inch thick, of fine dry sand, covered with another layer of the same thickness, on which another sheet of paper with plants is placed, and another layer of sand, till the box be full. The box is then set near a fire for two or three days, or till the plants be sufficiently dried.

Some vegetables are so tenacious of the vital principle, that they continue to grow during the process of drying; and others, as the heaths and firs, throw off their leaves. The immersion of the fresh specimen in boiling water, or the application of a hot-iron, counteracts both these effects; but even with every precaution, the colours of flowers, and the appearance of the leaves of many plants, undergo very great changes. Some yellow colours retain all their brilliancy and beauty; while others, as well as the whole plant, become black by drying. Blue colours generally fade; reds are not always permanent; and the natural aspect of most white flowers is altered.

When the specimens are dried, they are best preserved by securing them on paper with weak carpenter's glue, that they may be turned over without injury. When the stems are thick and heavy, the additional support of transverse slips of paper is necessary. A half-sheet of paper of a suitable size is to be allotted to each species; or, when the species occupies little room, two or more may be put upon the same half-sheet; and all the species belonging to the same genus are collected into one or more whole sheets; on the latter of which the name of the genus is written, and on the corner the name of the species, its place of growth, and other circumstances connected with its history. The specimens thus collected and arranged, are placed on shelves in a cabinet; and a dry room, without a constant fire, is recommended as most suitable for a herbarium.

The depredations of insects are peculiarly destructive to dried specimens, and especially *Ptinus fur*, a small beetle, deposits its eggs in the germens or receptacles of flowers, which are in a short time devoured by the maggots when hatched. To prevent their devastations, Dr Smith recommends a solution of corrosive sublimate of mercury in rectified spirits of wine, in the proportion of two drams to a pint, with the addition of a little camphor, as the most efficacious remedy. When the specimens are quite dry, and before they are pasted, the solution is applied with a camel-hair pencil. It is also found useful to mix a few drops of the solution with the glue which is employed for pasting the plants on the papers. This application, Dr Smith observes, not only keeps off all kinds of vermin, but greatly revives the colours of most plants, and gives the collection a pleasing air of freshness and neatness.

Chap. III. Structure and Functions of Vegetables.

The division of natural bodies into organised and inorganised, is sufficiently discriminative; the most perfect forms of inorganised matter exhibit no analogous characters to the varied and complicated structure of plants or animals. A striking diversity prevails in the mode of formation, or the growth and increase of the objects of these two great classes. In mineral bodies, the growth or increase is accomplished by the mere aggregation of the particles of matter already prepared, and according to the laws of affinity between these particles; and no new properties can be detected in the aggregate produced which are not found in the minutest particle of which it is composed. But in organised bodies, under which are comprehended vegetables and animals, the growth or increase is effected by a very different process. The substances of which they are composed are received into tubes or vessels, conveyed to all parts of the vegetable or animal, subjected in their progress to peculiar changes, and are converted into new forms, exhibiting properties and qualities which no chemical or mechanical operation could discover in the simple elements. New changes are produced, and new combinations are formed, none of which could be detected in the water, the earth, the air, the heat, or the light; all of which contribute their share to the progress and increase of organised bodies. Observing the remarkable diversity between the laws which regulate the operations of vegetables and animals and the established laws of chemical action, philosophers have naturally inferred the existence and influence of a different principle, called the *vital principle*, under whose power the wonderful and complicated phenomena of animals and vegetables are exhibited;—under whose power the effects of chemical or mechanical agents, which seem injurious, are counteracted;—under whose power what is beneficial is selected;—what is deficient is supplied, and what is redundant is cut off.

The division of organised bodies into vegetables and animals, although in both some points of resemblance may be traced, is, in general, sufficiently characteristic, when their form, structure, power of motion, constituent parts, and peculiar habits, are taken into consideration.

Sect. 1. *Of the Structure of Vegetables.*

A plant is composed of a root, stem, leaves, flowers, fruits, and seeds; and when these different parts are fully developed in the progress of vegetation, the plant is said to be perfect; when any of them are deficient or less obvious, it is called an imperfect plant. The root, concealed in the earth, conveys nourishment to the whole plant; the stem supports all the other parts, and when it is large and solid is called the trunk, which is divided into the wood and the bark; and the bark, forming the external covering, clothes the whole plant. The wood immediately under the bark is composed of concentric layers, which increase with the age of the tree; and the pith, a soft, spongy substance, occupies the centre of the stem. The leaves consist of fibres, arranged in a kind of net-work, which proceed from the stem and footstalks by which they are attached to the branches; the flowers are composed of different parts destined to the perfection of the the fruits and seeds; the fruits usually consist of a pulpy substance, containing numerous vesicles, traversed by great numbers of vessels, and seeds are constituted of a similar vesicular texture. Beside the parts now enumerated, plants contain different orders of vessels, as lymphatic vessels for the circulation of the sap, peculiar vessels which contain thick or coloured fluids, utriculi, or cells, and tracheæ, or spiral vessels.

Cuticle.—The bark is composed of three parts, the epidermis, parenchyma, and cortical layers. The epidermis, or cuticle, is a thin transparent membrane which forms the external covering of the bark, and is composed of fibres crossing each other. By means of this membrane, the plant is protected from the injuries of the air, and the processes of absorption and perspiration go on through its pores. It is of a very delicate texture on some plants, and coarse and thick on others, as on the trunk of the plane tree; readily peals off from some, as from the birch; and may be separated by maceration from others.

The cuticle is susceptible of extraordinary extension; for, during the growth of the plant, from the commencement of vegetation, it is stretched over its whole surface, without receiving any accession of matter, as the connection with the vascular or living part of the vegetable body seems to be altogether interrupted; but on the old trunks of most trees it may be observed to crack in all directions, and in many it is entirely obliterated.

In the currant tree, and in the elder, the cuticle is smooth, and scales off in large flakes; in the fruit of the peach, and the leaves of the mullein, it is covered with dense harsh wool; in the leaf of the white willow, it is of a silky texture; in the betony, and some other plants, it is extended into rigid hairs or bristles; on the fruit of the plum, and on many leaves, it is covered with a dry bluish powder, which repels the drops of rain; in the cork tree, the common maple, the Dutch elm, and the Constantinople hazel, the cuticle is covered with a singular fungous substance, well known as cork; and in grasses and reeds, siliceous earth has been detected by chemical analysis, and to this, no doubt, their hardness and fine polish are to be ascribed.

Cellular integument.—Under the epidermis or cuticle, a succulent cellular substance is deposited; it is usually of a green colour, at least in leaves and branches; exists almost universally; and has been observed in mosses and ferns. Leaves are composed almost entirely of a plate of this substance, covered on each side by the cuticle; and in this organ, the changes which are produced on the juices of plants, by light and air, are effected.

The bark.—Next to the cellular integument lies the bark, which in plants or branches of one year old consists of a single layer, scarcely to be distinguished from the wood; but in older branches, and the trunks of trees, the number of layers is equal to the number of years during which the plant has existed. The innermost layer is called *liber*. The bark is composed of numerous woody fibres, which chiefly run in a longitudinal direction, and when macerated in water exhibit a beautiful structure resembling net-work. The lace-bark tree, *Daphne laghetto*, a native of Jamaica, presents a remarkable example of this structure, which has been already noticed in the description of that plant.

The peculiar virtues or qualities of plants chiefly reside in the bark, and especially in those layers which are next to the wood; it is here that the resin of the fir, the astringent qualities of the oak, and the aromatic oil of the cinnamon, are found.

Wood.—The wood which lies immediately under the bark, is composed of numerous concentric layers which increase with the age of the plant, and may be separated into thinner layers, which consist of longitudinal fibres. The wood which is next the bark is softer and whiter, and is hence called *alburnum* or white-wood, and known to workmen by the name of Sap; the interior part of the trunk is browner and harder, and is denominated the perfect wood. In the laburnum the concentric layers which constitute the alburnum are yellowish, and the perfect wood is brown. A tranverse section of lignum-vitæ affords a good example of the same diversity of appearance.

Pith.—The medulla or pith occupies the centre of the trunk or stem of the plant, and in growing stems or branches is a tolerably firm juicy substance; but when the same parts are fully grown, it becomes extremely light and cellular. Many of the grasses and umbelliferous plants have always hollow stems, lined only with a thin smooth coating of pith. Of the nature and functions of the pith, physiologists have entertained very different opinions; some have supposed that it performs no important office in the economy of plants, and others regard it as the seat of life and the source of vegetation; but whatever be its nature and functions, as it is most vigorous and abundant in young and growing branches, it cannot be doubted that it performs some essential part. Mr Knight supposes that the pith is a reservoir of moisture to supply the leaves when an excess of perspiration takes place; but it has been remarked by Dr Smith, that all the moisture in the pith of a whole branch would be too little in some cases to supply one hour's perspiration of a single leaf.

Vessels of plants.—Plants are furnished with different kinds of vessels, which are distinguished from each other by their course, situation, and uses. The lymphatic vessels, which serve for the circulation of the sap, are chiefly distinguished in the woody part of the plant. The peculiar vessels which contain thick or coloured fluids lie immediately under the bark. Some of these proper vessels are placed between the cuticle and the bark; and some forming oval rings, and filled with the peculiar juices of the plant, are situated in the interior part of the bark.

Another set of proper vessels is distributed in the *alburnum*, nearer to the centre of the trunk, and sometimes in the perfect wood.

The *utriculi*, or cells, constitute another set of vessels, vary in form, colour, and magnitude in different vegetables, and exist in the roots, the bark, leaves, and flowers. They seem to resemble a flexible tube slightly interrupted with ligatures nearly at equal distances, while a free communication is preserved through its whole length. The tracheæ or spiral vessels appear in the form of fine threads, and may be drawn out to a considerable length without breaking. These vessels are very numerous in all plants, form a kind of ring underneath the bark, and are distributed in distinct bundles in trees, shrubs, and herbaceous plants. These spiral vessels are easily detected in succulent plants, as in the leaf stalks of elder, syringa, and other shrubs; and in many plants of a herbaceous nature, as in the pæony and many of the lily tribe.

Spiral vessels were supposed by Malpighi and Grew to be air vessels, performing a similar office in plants, to the lungs of animals; but from the curious experiments and observations of Mr Knight, the fluids destined to the nourishment of the plant being absorbed by the root, are conveyed to the leaves by these vessels; and from their situation near the pith he has given them the name of central vessels.

Seeds.—The seeds from which the future plant proceeds is composed of different parts; of these parts the embryo, or germ, to which Linnæus gave the name of *corculum*, or little heart, is the most essential. This part is sufficiently obvious in some seeds, as the bean, the pea, and the lupine; and its internal structure, before the commencement of vegetation, is very simple. The cotyledons, or seed-lobes, are immediately attached to the embryo, and indeed are to be considered as forming part of it. In most seeds the cotyledons are two in number; but some seeds, as those belonging to the grass and corn tribe, the palms, and some other plants, have only one cotyledon, while others have three or more; and hence the division of plants suggested by this peculiarity of structure in the seeds, into monocotyledonous, dicotyledonous and polycotyledonous. In those plants the seeds of which have only one cotyledon, the greater part of the substance of the seed is composed of a farinaceous, fleshy, or horny substance, called albumen or white. When seeds of this description germinate, the cotyledon never rises out of the ground, or performs the office of leaves; but in plants whose seeds have two cotyledons, they rise out of the ground, and being formed from the seed itself, are called seminal or seed leaves. In some cases the seed leaves wither and decay as soon as the other leaves begin to unfold; but in other cases they continue long, and remain green and vigorous after the plant has made considerable progress; this may be observed in the yellow lupine. The cotyledons are abundantly obvious in the garden bean after it has begun to vegetate, and the embryo is seen to push out from between them.

The appendages of many seeds, and the peculiar structure of some seed-vessels, are admirably calculated to promote their dispersion; for this purpose seeds are furnished with wings, spines, hooks, and scales. The downy appendage of many seeds of syngenesious plants, as is familiar to every one in the dandelion, wafts them through the air; the elastic power of the seed-pods of other plants, projects their contents to a considerable distance; and the barbed structure of some seeds retains them in the soil, while the uncoiling of the attached awn forces them deeper.

Sect. II. *Functions of Vegetables.*

When the perfect seeds of a plant are exposed to the influence of certain agents, they undergo a very remarkable change, in the progress of which, plants exactly similar to those from which they originated are produced.

Germination.—The first change which is observed in seeds when they are placed in certain circumstances, is called germination. Heat, air, and moisture, are necessary to this process. No vegetation whatever takes place when the temperature is at the freezing point, and very little till it rises many degrees above it. Air is no less requisite for the germination of seeds; when it is entirely excluded, as in the vacuum of an air pump, no change takes place. Moisture is also necessary in this process; but in most cases water must be applied in a regulated and moderate quantity,—for, excepting the seeds of aquatic plants, which possess peculiar habits, most seeds, when exposed to excessive moisture, are deprived of their vegetative power. The exclusion of light is favourable to the vegetation of seeds, and hence it is that their germination is greatly promoted by covering them with the soil.

When a seed begins to germinate, the first change observed is the increase of size by the absorption of moisture; the radicle, or little root, pushes out and stretches downwards into the earth, from which it conveys nourishment for the growth of the future plant. Another part, called *plumula*, shoots upwards, and finally expands into leaves and branches; but these remarkable effects are owing to certain changes which take place within the seed. The absorption of the oxygen of the atmosphere, the evolution of carbonic acid gas, by the combination of the oxygen with the carbone of the seed, and the conversion of the farinaceous matter into a saccharine substance, which is destined for the nourishment of the embryo plant, are the first changes observed in the germination of seeds. The cotyledons, or seed-lobes, are to be regarded as store-houses of food for the young plant, before the evolution of its parts are fully completed, to enable it to derive nourishment from the earth.

Roots.—The roots of plants are intended to retain them firmly in the soil, and at the same time to derive nourishment for their support. The root is composed of two parts, denominated *caudex*, or body, and *radicula*, or fibre, the latter of which, as it alone imbibes nourishment, is essential to the plant. The turnip and the carrot form the *caudex*, or body of the root, while the fibres which proceed from them are to be considered as the proper roots.

The fibrous extremities of roots, which draw nourishment from the earth, are produced annually, and these extremities have a peculiar structure; for when the extremities of the fibre are cut off, the vegetation of the plant ceases till new fibres are formed; and hence the practice of cutting off most of the fibres is in many cases extremely prejudicial. The peculiarity of structure alluded to may be observed in the fibres of bulbous roots which blow in water, in which case the extremity of each fibre seems to be included in a kind of fringed bag.

Stems, &c. of plants.—The stem, stalk, or trunk of a vegetable, thus variously denominated in different kinds of plants, forms a support for the leaves and flowers, and a necessary communication between the root and those parts which are elevated above the surface of the earth, and in which the most important functions of vegetation are accomplished. The stems of plants are not less various in form, magnitude, and consistence than the character and habits of the different kinds of vegetables to which they belong. This diversity affords many important distinctions for botanical classification, as well as many curious topics for physiological inquiry.

The branches of trees or shrubs, which constitute a minuter division of the trunk or principal stem of the vegetable, may be regarded as a new order of stems, whose roots are attached to a ligneous base, and thus form the necessary communication between the leaves and the source of nourishment.

The general aspect of a plant depends, in a great measure, on the distribution of the branches, as they spring from the trunk in a spiral direction, opposite to each other, in whorls, disposed irregularly, or from two sides of the trunk only, and form with it more or less acute angles. On the same plant the branches are observed to be arranged in very different, and almost opposite directions. In a large tree the lower branches are bent towards the earth, some spread out horizontally, and those towards the summit of the tree rise nearly in a perpendicular direction; but the disposition of the whole is such that the action of the air and light, of so much importance to the health and vigour of the vegetable, may be the least interrupted. Influenced by the same cause, a plant in a shady place inclines all its branches to that side where the action of air and light is most powerful; and plants, confined in a hot-house, turn all their leaves and branches towards that side from which the light proceeds.

According to Schabol, as quoted by Mirbel, five different kinds of branches may be distinguished in fruit-trees,—a distinction of no small importance in their culture and management. In the first kind the surface is smooth, the vessels run in a straight direction, and are easily separated; they bend without breaking straight across, and produce only wood. By practical gardeners such shoots are called the *wood*. 2. In the second kind of branches the base is wrinkled and perforated with small holes, the texture is more complicated, the vessels more numerous, and the juices of greater consistence; these are the fruit branches; they produce flower-buds, and break clean across when they are bent. 3. Another set of branches bear some resemblance to the first, but they are less permanent, because they have their origin only in the bark; they are denominated branches of *spurious wood.* 4. In the fourth order of branches the base is broad, the bark is brownish and rough, their buds are black and thinly set; they have their origin in the bark, and are nourished at the expence of the useful branches; they push out rapidly, and have a short duration. 5. The fifth kind of branches, which are not particularly characterised, are described as being useless to vigorous trees, and injurious to those whose vegetative powers are feeble. They draw to themselves a large portion of nourishment, and exhaust the vegetable on which they exist.

Buds.—As the trees of tropical regions, where vegetation is never interrupted, are destitute of buds, this part of the vegetable structure, in which the rudiments of a plant remain in a dormant state, till the influence of those agents which produce its evolution commences, is a necessary preservative in cold countries. The buds of trees and shrubs are formed during the summer in the bosoms of the leaves. In their structure and distribution they are remarkably uniform in the same species, but a great diversity prevails in their situation and forms in different tribes of plants. They are composed of a number of scales, which are closely wrapped upon each other, and unfold the embryo plant or branch. To enable them to accomplish the purpose for which they are destined, many buds are furnished with some additional covering, as a coat of wool, or of a gummy or resinous secretion. Thus constructed and protected, buds are enabled to resist very great degrees of cold; for it is only when the vegetative process has commenced, when they begin to unfold their leaves, that they sustain injury from the sudden changes of a variable climate.

Buds derive their origin from the *alburnum*, or white wood, according to the observations of Mr Knight; but perhaps this is liable to certain modifications, if the remarks of Schabol, formerly detailed, on the different kinds of branches be well founded. In some tribes of plants the same buds produce both leaves and flowers, but in others the leaves and flowers appear in different buds. The bulbs, or as they are, with little propriety, denominated roots, of certain tribes of plants, as the hyacinth, the lily, and the tulip, are true buds; and in some of them, as in the tulip, the future flower is distinctly formed, and only requires the influence of the necessary agents of heat, air, and moisture, for its complete evolution.

Every bud may be considered as a distinct individual performing its functions, when the influence of the proper agents is exerted, independent of the parent stem, or of any other part of the plant, excepting in the circumstance of deriving its nourishment from that source. Thus, if the branch of a vine, whose root is exposed to the open air, be introduced into a hot-house in the middle of winter, the vegetative process will immediately commence, and proceed with vigour, and if the proper temperature be continued, leaves, flowers, and fruit may be produced while every other part of the tree remains in a dormant state.

Leaves.—The leaves of plants, not only contribute to their beauty and elegance, but perform functions of essential importance in the process of vegetation. Deprived of its leaves, no tree brings its fruit to maturity, as is too often experienced in the ravages of the caterpillar on the gooseberry; and if by any accident a tree has lost its leaves, the progress of its growth is interrupted till it is again clothed with foliage.

A leaf is composed of a double layer of the fibres and vessels of the footstalk, between which is interposed a plate or layer of the *parenchyma* or cellular texture. Leaves, it has been long observed, and proved by decided experiments, transpire a considerable quantity of moisture, and in some cases this quantity was little inferior to the moisture absorbed. It is greatest during sunshine and warm weather, is much interrupted during the night, and entirely checked by cold. In an experiment by Dr Hales, a plant of sun-flower, *Helianthus annuus*, lost nearly two lbs. weight in twelve hours of a hot dry day; in a dry night, the diminution of weight was only about three ounces; in a moist night, no perceptible difference was observed; and in a rainy night it gained two ounces. The matter excreted by the leaves of plants is of very different qualities. In some it is aqueous, in some of a saccharine nature, and in others it is glutinous, resinous, or waxy.

The sap of plants flows from the root towards the branches and leaves; and in the leaves it undergoes peculiar changes, in consequence of part being exhaled, and of the absorption of different principles, which, combining with it, contribute to the changes that are effected. During these changes the peculiar juice of the plant is prepared, which, in its progress from the leaves towards the roots, deposits those ingredients which produce all the variety of substances which are detected by the remarkable diversity of odour, taste, and consistence. The exhalation of a portion of the moisture taken in by the roots, and the absorption and decomposition of carbonic acid gas, by which the carbone is retained in the plant and the oxygen is given out, constitute one part of the functions of leaves. These processes are most vigorous during the day, and particularly during bright sunshine; but in the night they are reversed. Carbonic acid gas is given out, and moisture and oxygen gas are absorbed; and this absorption and moisture is chiefly effected in many plants by the under surface of the leaves.

The effects of light on vegetables are very remarkable. When it is entirely excluded, although they enjoy the influence of air, heat, and moisture, they never acquire their rich green colour, but remain of a pale, sickly white. The familiar practice of blanching or whitening celery, affords a good illustration of this fact; and it is not only the colour, but the smell and taste undergo equal changes.

Sleep of plants.—When the influence of those agents which have a powerful effect on vegetables is withdrawn, many plants exhibit a very remarkable change in their aspect. This is particularly the case with plants which have pinnated leaves. During the night, and sometimes in dark cloudy weather, the leaves droop or fold over each other; this has been called the sleep of plants, and it has been supposed that it may be a kind of necessary repose in some way useful to the vegetable constitution. A similar change takes place in other plants from mechanical impulse, as in the sensitive plant: the leaves of which, by the slightest touch, close together, and exhibit the same appearance as those plants which are supposed to be under the influence of sleep.

Heat of plants.—During the chemical changes that take place in plants, it cannot be doubted that heat is evolved or abstracted; and it is extremely probable that plants, as well as animals, have the power of regulating, although in a lower degree, the excesses of temperature to which they are exposed. The snow which falls on the leaves and stems of living plants melts sooner than on dead matter of the same kind,—an obvious proof that the temperature is higher; but the heat of vegetables is so much superior to that of the atmosphere, as to be indicated by the thermometer. A remarkable fact is stated by Senebier with regard to the increased temperature of the white-veined variety of the *Arum maculatum* in a certain period of its growth, when the flower was for a few hours very hot; it was perceptible from three or four o'clock in the afternoon till 11 or 12 at night; and when the temperature of the air was 14 or 15 degrees of Reaumur's thermometer, the heat of the plant, when it was highest, was seven degrees above it. This curious fact, as is justly observed by Dr Smith, is well worthy of attention, and may perhaps be observed in other plants.

Duration of plants.—Many plants, as soon as they have ripened their seeds, which is accomplished by some in one season, by others in two, cease to vegetate; and hence such plants have been denominated *annuals* and *biennials*,—terms expressive of their duration for one or two years; but other plants live for a great length of time, and continue to produce seeds and fruit for many successive seasons; and hence such plants have been called *perennials*. This diversity of duration exhibits a wonderful and endless variety among the vegetable tribes. The humble annual springs up, displays its leaves, and flowers, and forms perfect seeds, and thus, within the short period of a few months, passes through the whole progress of its existence; while the stately oak rears its lofty head, and continues to be the glory and pride of the forest for hundreds of years.

Those who wish to extend their knowledge of the structure and functions of plants may consult with advantage, *Senebier Physiologie Vegetale;* Mirbel on the same subject; Smith's Introduction to Botany; Willdenow's Introduction; and, for the classification and description of plants, Willdenow's Species Plantarum, Brown's *Prodromus Plant. Nov. Holland;* and the Appendix to Flinder's Voyage, by the same excellent botanist; and, for British plants, Smith's *Flora Britannica*, Withering's Botanical Arrangement, and Lightfoot's *Flora Scotica.*

GENERA ILLUSTRATED IN THE PRECEDING TREATISE, ARRANGED UNDER THEIR CLASSES.

Genera.

Fuchsia, Fuchsia.
Erica, Heath.
Daphne, Mezereon, or Spurge Olive.
Mœhringia, Mountain Chickweed.
Paullinia, Supple Jack.
Coccoloba, Seaside Grape.
Polygonum, Persicaria, or Bistort.
Paris, Herb Paris.
Adoxa, Moschatel.

IX. Enneandria. Page 728.

Laurus, Bay, Cinnamon, and Camphor Tree.
Anacardium, Cashew-nut Tree.
Rheum, Rhubarb.
Butomus, Flowering Rush.

X. Decandria. Page 729.

Sophora, Sophora, or Bead Tree.
Cæsalpinia, Brazil Wood.
Hæmatoxylon, Logwood.
Swietenia, Mahogany Tree.
Guaiacum, Lignumvitae.
Ruta, Rue.
Quassia, Quassia Tree.
Dionæa, Venus' Fly Trap.
Melastoma, Melastoma, or Indian Currant Bush.
Andromeda, Wild Rosemary, or Sorrel Tree.
Rhododendron, Rhododendron.
Kalmia, Kalmia.
Arbutus, Arbutus, or Strawberry Tree.
Hydrangea, Hydrangea.
Saxifraga, Saxifrage.
Dianthus, Clove or Pink.
Stellaria, Chickweed and Stichwort.
Arenaria, Sandwort.
Sedum, Stonecrop.
Oxalis, Wood Sorrel.
Agrostemma, Corn Cockle.
Lychnis, Catchfly, and Campion.
Cerastium, Mouse-ear Chickweed.
Spergula, Spurrey.
Phytolacca, Redweed, or Spanish Calalue.

XI. Dodecandria. Page 733.

Asarum, Asarabacca.
Rhizophora, Mangrove.
Lythrum, Loose-strife.
Halesia, Snowdrop Tree.
Heliocarpus, Sunseed.
Agrimonia, Agrimony.
Reseda, Dyer's Weed, and Mignonette.
Euphorbia, Spurge.
Cephalotus, Pitcher-plant.
Sempervivum, House-leek.

XII. Icosandria. Page 734.

Cactus, Creeping Cereus, or Melon Thistle.
Philadelphus, Mock Orange.
Myrtus, Myrtle, and Jamaica Pepper Tree.
Eucalyptus.
Metrosideros.
Psidium, Guava Tree.
Amygdalus, Almond and Peach Tree.
Prunus, Sloe and Plum Tree.
Mespilus, Hawthorn and Medlar Tree.
Pyrus, Pear and Crab Tree.
Mesembryanthemum, Fig Marygold.
Spiræa, Dropwort and Meadowsweet.
Rosa, Rose Tree.
Rubus, Raspberry and Bramble.
Fragaria, Strawberry.
Potentilla, Silver Weed.
Geum, Avens, or Herb Bennet.
Calycanthus, Allspice Tree.

XIII. Polyandria. Page 736.

Papaver, Poppy.
Cistus, Rock-rose.
Capparis, Caperbush.
Sanguinaria, Bloodwort.
Sarracenia, Side-saddle Flower.
Nymphæa, Water lily, or Lotus.
Tilia, Lime or Linden Tree.
Corchorus, Broomweed or Jews Mallow.
Thea, Tea Tree.
Bixa, Annotto.
Pæonia, Pæony Rose.
Delphinium, Lark's Spur.
Aconitum, Monks-hood.
Wintera, Winther's Bark Tree.
Aquilegia, Colombine.
Stratiotes, Water Soldier.
Anemone, Anemone, or Pasque-flower.
Ranunculus, Ranunculus, Spearwort and Pilewort.
Liriodendron, Tulip Tree.
Annona, Sour and Sweet Sop.

XIV. Didynamia. Page 738.

Ajuga, Bugle.
Teucrium, Wood sage.
Mentha, Mint.
Lamium, Dead-nettle.
Stachys, Hedge-nettle or Woundwort.
Prunella, Selfheal.
Rhinanthus, Horse-rattle.
Euphrasia, Eyebright.
Antirrhinum, Snapdragon.

Genera.

Digitalis, Foxglove.
Linnæa, Linnæa.
Bignonia, Trumpet-flower.
Crescentia, Calabash Tree.
Melianthus, Honey-flower.

XV. Tetradynamia. Page 739.

Draba, Whitlowgrass.
Thlaspi, Shepherds Purse.
Lunaria, Moonwort or Satin-flower.
Crambe, Sea-kale.
Lepidium, Garden Cress.
Cochlearia, Scurvygrass.
Iberis, Candytuft.
Cardamine, Lady's Smock.
Sisymbrium, Water-Cress and Isle of Man Rocket.
Erysimum, Hedge Mustard, or Yellow Rocket.
Cheiranthus, Wallflower.
Brassica, Rape, Turnip, Cabbage.
Sinapis, Mustard, Charlock.
Raphanus, Wild Radish, or Jointed Charlock.

XVI. Monadelphia. Page 740.

Tamarindus, Tamarind Tree.
Sisyrinchium.
Ferraria, Tiger-flower.
Erodium, Stork's-bill.
Pelargonium, Crane's-bill.
Aitonia, Aitonia.
Geranium, Geranium or Crane's-bill.
Bombax, Cotton Tree.
Gossypium, Cotton Plant.
Malva, Mallow.
Lavatera, Lavatera or Tree Mallow.
Hibiscus, Syrian Mallow, and Indian Sorrel.
Camellia, Japan Rose.
Alcea, Hollyhock.

XVII. Diadelphia. Page 742.

Fumaria, Fumitory.
Polygala, Milkwort.
Spartium, Broom.
Ulex, Furze, or Whin.
Hedysarum, Saint Foin.
Lupinus, Lupine.
Pisum, Pea.
Phaseolus, Kidney Bean.
Lathyrus, Sweet Pea.
Vicia, Vetch and Bean.
Trifolium, Trefoil.
Indigofera, Indigo Plant.
Cytisus, Laburnum, or Trefoil Tree.

XVIII. Polyadelphia. Page 743.

Theobroma, Chocolate-nut Tree.
Monsonia, Monsonia.
Citrus, Citron, Orange, Lemon, &c.
Melaleuca, Cajeput Tree.
Hypericum, St John's Wort.

Genera.

XIX. Syngenesia. Page 743.

Leontodon, Dandelion.
Hieracium, Hawkweed.
Arctium, Burdock.
Carduus, Thistle.
Eupatorium, Hemp Agrimony.
Bellis, Common Daisy.
Chrysanthemum, Ox-eye Daisy.
Solidago, Golden-rod.
Senecio, Groundsel.
Tussilago, Colt's-foot.
Aster, Starwort.
Anthemis, Camomile.
Achillea, Sneezewort.
Centaurea, Knapweed, or Blue-bottle.
Rudbeckia, Rudbeckia.
Helianthus, Sun-flower, or Jerusalem Artichoke.
Calendula, Garden Marygold.
Echinops, Small Globe Thistle.

XX. Gynandria. Page 745.

Orchis, Butterfly-flower.
Ophrys, Twayblade.
Cypripedium, Ladies Slipper.
Limodorum, Limodorum, or Jamaica Saloup.
Epidendrum, Epidendrum, or Vanilla.
Nepenthes, Nepenthes.
Passiflora, Passion-flower.

XXI. Monœcia. Page 746.

Zannichellia, Horn Pond-weed.
Artocarpus, Bread-fruit Tree.
Lemna, Duckweed.
Sparganium, Bur-reed.
Carex, Sedge Grass.
Typha, Cat's-tail.
Hernandia, Jack-in-a-box Tree.
Urtica, Nettle.
Buxus, Box-tree.
Betula, Birch and Alder Tree.
Morus, Mulberry and Fustick Tree.
Amaranthus, Amaranth, or Calalue
Fagus, Chesnut and Beech Tree.
Quercus, Oak Tree.
Juglans, Walnut Tree.
Corylus, Hazel-nut Tree.
Calla, Calla.
Arum, Arum, or Wake-robin.
Pinus, Pine, or Fir Tree.
Ricinus, Castor-oil nut Plant.
Jatropha, Cassada Plant.
Hura, Sand-box Tree.
Hippomane, Manchineal Tree.
Cucumis, Cucumber and Melon.

XXII. Diœcia. Page 750.

Vallisneria, Vallisneria.
Salix, Willow.
Empetrum, Crow Berry.
Ruscus, Butcher's Broom.
Viscum, Misseltoe.
Myrica, Gale and Candle-berry Myrtle.
Trophis, Ramoon Tree.
Cannabis, Hemp.
Humulus, Hop Plant.
Myristica, Nutmeg Tree.
Populus, Poplar Tree.
Rhodiola, Rose-root.
Mercurialis, Dog's Mercury.
Carica, Papaw Tree.
Juniperus, Juniper.
Taxus, Yew Tree.

XXIII. Polygamia. Page 752.

Musa, Plantain and Banana.
Mimosa, Gum Arabic Tree, Sensitive Plant.
Atriplex, Orache, or Sea Purslane.
Ficus, Fig and Banyan Tree.

XXIV. Cryptogamia. Page 753.

Equisetum, Horse-tail.
Ophioglossum, Adder's-tongue.
Osmunda, Moonwort, or Flowering Fern.
Lycopodium, Club-moss.
Polypodium, Polypody.
Aspidium, Male, or Shield Fern.
Blechnum Rough Spleenwort.
Scolopendrium, Hart's-tongue.
Asplenium, Sea Spleenwort.
Lonchitis, Hairy Spleenwort.
Adiantum, Maiden-hair.
Lindsæa, Lindsæa.
Pteris, Brakes.
Sphagnum, Bog Moss.
Phascum, Earth Moss.
Gymnostomum, Beardless Moss.
Splachnum, Gland Moss.
Encalypta, Extinguisher Moss.
Trichostomum, Fringe Moss.
Tortula, Screw Moss.
Orthotrichum, Bristle Moss.
Neckera, Neckera.
Mnium, Spring Moss.
Funaria, Cord Moss.
Bartramia, Bartramia.
Polytrichum, Hair Moss.
Jungermannia, Star-tip.
Marchantia, Liver-green.
Lichen, Liverwort.
Fucus, Sea-weed.
Agaricus, Mushroom.
Lycoperdon, Truffle, Puff-ball.

Palms.

Chamærops, Dwarf Palm.
Thrinax, Palmeto Royal.
Borassus, Fan Palm.
Corypha, Mountain Palm.
Phœnix, Date Palm.
Areca, Mountain Cabbage, Betel Nut.
Cocos, Cocoa-nut, Prickly Pole.
Ceroxylon, Wax Palm.
Cycas, Sago Palm.

BOTANY-BAY, a spacious bay on the south-east coast of New Holland, which derived its name from the great profusion of plants which were found by the naturalists who first visited that distant region. See New Holland.

BOTARGO, a peculiar kind of sausage, which is made of the milts and roes of the mullet, a fish which is common in the Mediterranean. This kind of sausage, which is usually eaten with olive oil and lemon juice, is in great request in the southern parts of Europe.

BOTHNIA, a province or district of Sweden, which is divided into two parts, denominated from their position East and West Bothnia.

East Bothnia, which stretches along the east side of the gulph of the same name, is about 300 miles long, and varies from 70 to 200 miles in breadth. A mountainous ridge forms the eastern boundary between Russia and Finland Proper. On the southern coast the land is low and marshy, but in some places the soil is remarkable for its fertility; and from the great length of the days in the middle of summer, or rather from the absence of night during that period, for the sun is visible for some weeks at midnight, corn has been known to ripen in six or seven weeks. The lakes and rivers abound with salmon. The population is estimated at 80,000; and fishing and agriculture afford the chief occupations to the inhabitants. Cattle, butter, dried salmon, pitch, tar, and timber, are enumerated as the principal exports.

West Bothnia lies on the west side of the gulph of Bothnia, and is bounded on the north and west by Lapland, and on the south by Angermannia. This district is in many places mountainous, but in others the soil is fertile and productive. The labours of agriculture, fishing, hunting, and the working of mines of copper and iron, chiefly occupy the industry of the inhabitants. Beside the commodities enumerated among the exports of East Bothnia, the skins of various wild animals, as those of the black and blue fox, the bear and wolf, the ermine, and the rein-deer, furnish the materials of a profitable commerce to the inhabitants of this district. Umea, Lulea, and Tornea, are the principal towns.

BOTHNIA, Gulph of, a branch of the Baltic, which is bounded on all sides by the territory of Sweden, excepting on the south, where the isles of Aland form the separation between this gulph and the Baltic sea. The length from north to south is estimated at 350 miles, and the breadth from east to west from 50 to 140 miles. In the winter season it is often frozen over, and thus forms an easy communication between the opposite coasts.

BOTTLE, supposed to be derived from a barbarous Latin word, is a small vessel for containing liquors, which, in different nations and periods of society, has been constructed of leather, stone-ware, and glass. The skins of animals seem to have been universally employed by the earlier inhabitants of eastern countries; and among the Jews, from the allusions in Scripture, it appears to have been the common practice; and hence the expression used by our Saviour, of "putting new wine into old bottles," from the danger of bursting by fermentation and increase of bulk, admits of an obvious explanation.

Earthen jars were employed by the ancient Romans for preserving their wine. The use of glass for this purpose has not been traced farther back than the 15th century. Common bottles, so universally employed in all European countries, and forming an extensive branch of manufacture, are made of coarse, greenish-coloured glass. Glass bottles of a finer quality, and thinner in the sides, are secured from external injury with a covering of twisted straw, or wicker-work, and then come under the denomination of flasks; such are the thin bottles which are brought from the southern parts of Europe with olive oil.

BOTTOMRY, a term in commercial affairs, which denotes a kind of contract, in the form of a mortgage of a ship, by which the owner of the vessel borrows money to enable him to complete the voyage, and pledges the keel or bottom of the ship, from which circumstance the contract derives its name, as a security for repayment. A contract of this nature, as in many cases it must be highly beneficial to trade, is allowed to be valid among all commercial nations. If the ship be lost the lender loses his money, but if it return in safety the principal as well as the premium or interest agreed upon, however it may exceed the legal rate of interest, is repaid. In this case, the ship and tackle, as well as the person of the borrower, are answerable for the money lent. But if security for the loan be given on the goods and merchandise which are to be sold or exchanged in the course of the voyage, then the borrower only is personally bound to fulfil the contract; and, in such a case, he is said to take up the money at *respondentia.*

Contracts of this kind were not unknown to the ancients; and laws for their regulation, enacted by the Romans, are still extant. In modern times, and particularly in Britain, contracts of bottomry and respondentia have been the subjects of legislative regulation. See Marshall on *Insurance;* Parke on *Marine Insurances;* and Jacob's *Law Dictionary.*

BOTTS, a kind of worms which are produced in the intestines of the horse, and which appear to be the *larvæ* of the gad-fly. See *Oestrus* under Entomology.

BOUGUER, Peter, an eminent French mathematician and natural philosopher, was born at Croisic, in the department of Lower Loire, in 1698, early commenced the study of mathematics under the tuition of his father, who was royal professor of Hydrography, and in his fifteenth year succeeded, on the death of his father, to the same situation, the duties of which he is said to have performed with great ability. A memoir on the Masting of Ships, presented to the Academy of Sciences in 1727, entitled him to the prize offered by that learned body for the best treatise on this subject; and in two years afterwards he was honoured with a similar mark of distinction for his memoir on the best method of ascertaining the height of the stars at sea.

In the year 1730 M. Bouguer removed to Havre; in 1731 was appointed associate geometer; and in 1735 was nominated pensioner astronomer. In the same year he embarked with his associates, Godin, Condamine, and Jussieu, for South America, for the purpose of measuring a degree of the meridian; and after an absence of nine years, during which he and his companions experienced the severest hardships and privations on the heights of the Andes, he returned to Europe in 1744. Five years afterwards he published his great work on the figure of the earth, determined from the observations made in Peru, and was involved in a controversy with his fellow traveller Condamine, who charged him with partiality in the distribution of the merit due to his associates in the undertaking. Condamine succeeded in securing the largest portion of the favour of the public who took any part in the dispute. Bouguer, who, it is said, was of a suspicious and envious disposition, was severely mortified at the issue of this controversy, and suffered much in his bodily health. He died in 1758, when he had reached the 60th year of his age. Beside the works already alluded to, he was the author of various treatises connected with physics and navigation, which appeared in a separate form, or in the Memoirs of the Academy.

BOULACK, or BULAK, a town of Egypt, which stands on the banks of the Nile, two miles west from Grand Cairo, has become a place of considerable commercial importance, and is the chief port of Lower Egypt. A customhouse, a spacious bazar or market-place, magnificent public baths, and magazines or warehouses for the accommodation of merchants, are the principal public buildings. The surrounding country is covered with beautiful gardens, which afford an abundant supply of delicious fruits, and all kinds of useful vegetables. But the invasion of Egypt by the French in 1799 was fatal to this town, for it was almost entirely destroyed by their army.

BOULOGNE, called also BOULOGNE SUR LA MER, from its situation on the sea-coast, a seaport town in the department of the straits of Calais in France, and formerly the capital of the province of Boulognois in Picardy. Boulogne is a place of great antiquity. It is supposed to be the *Portus Iccius* of Julius Cæsar, from which he embarked for the invasion of Britain; a light-house, or pharos, built by Caligula, was repaired by the emperor Charlemagne in the beginning of the ninth century, but was at last neglected, and about the middle of the 17th century became a heap of ruins.

Boulogne stands at the mouth of the river Liane, and is divided into an upper and lower town; the former is on the declivity of a mountain, is surrounded with a wall, and, before the revolution, was chiefly inhabited by the nobility. The lower town, occupied by persons engaged in trade, is nearer the sea, and is of an irregular form, with narrow winding streets. The harbour is of small extent, and is defended by a fort and batteries; but the entrance is incommodious, the depth of water small, and the roadstead is unprotected and insecure. The inhabitants are estimated at 10,000, a large proportion of which is occupied in the herring and mackarel fishery, which, for nearly three centuries, has been an object of importance to this place. Some manufactures of woollen and linen are carried on; but the exportation of Burgundy and Champaigne wines, and the smuggling of brandy, cambric, and other contraband goods, to the shores of Britain, constitute the greater part of its commerce. Boulogne is 20 miles S. E. from Calais, and 55 miles N. E. from Paris.

BOUNTY, a premium, or pecuniary reward, paid out of the public revenue, for the encouragement of navigation and shipping, or particular branches of agriculture or trade; of the first kind are the bounties which are paid for the encouragement of the whale and herring fishery; and of the latter description are those which are allowed for the exportation of grain in certain cases, and for the encouragement of rising manufactures. Of the beneficial effects of premiums of this description some diversity of sentiment prevails; but, in general, the opinions of the most respectable writers on political economy are unfavourable to the practice. This subject is fully discussed in the works of Dr Smith and Mr Malthus.

BOURBON, an island in the Indian ocean, in south latitude 20° 52′, and east longitude 55° 30′, about 100 miles S. W. from Mauritius, and 360 east from Madagascar. When it was first discovered by the Portuguese it was called Mascarenhas. The greatest length of this island is stated at 14 leagues, and the circumference pursuing the windings of the coast, is nearly 40 leagues. The surface of the island of Bourbon is said to be chiefly composed of two volcanic mountains, one of which rises 9000 feet above the level of the sea. The mountain called Gros Morne towards the northern part of the island has never been known, since its discovery by Europeans, to be in a state of activity, and its sides are clothed with luxuriant vegetation. But scarcely a year passes without a furious eruption from the mountain called Volcano in the southern district, and its ravages are strongly marked by the sterility and desolation of the surrounding territory, which is expressively denominated the *burnt land*.

The great inequality of surface produces great diversity of climate. The lofty peaks of the mountains are covered with snow in the winter season; in a lower region the agreeable coolness of the temperate zones prevails, while the full influence of a vertical sun is felt on the sea-coasts. A lake, half a mile in diameter, occupies the central part of the island, and seems to depend for the supply of its waters on the rains, for in some seasons it is quite dry. The rivers also derive their waters from the same source, or from the melting of the snows on the elevated summit of the mountains. Two remarkable plains lie between the loftier mountains. The plain Des Cafres, rising between 3000 and 4000 feet above the level of the sea, presents a desolate aspect; a few diminutive shrubs and stunted heaths are its only productions. But the Plain of Palms, so named from the profusion of mountain cabbage, or betel-nut palms, which cover its surface, is adorned with all the luxuriance of the richest vegetation. Hurricanes, as in other tropical regions, annually produce their destructive ravages in the isle of Bourbon.

All the fruits of tropical countries are abundant; and coffee, sugar, cotton, and cloves, are successfully cultivated. Corn and rice are raised in considerable quantities; a large proportion of which is exported to the Mauritius to supply its inhabitants with provisions.

The population of Bourbon in 1717 was estimated at 2000, of which 900 were whites and free persons, and 1100 were slaves; but in 1810, when it fell under the dominion of Great Britain, the number of inhabitants was computed at 90,000, of which 16,000 are stated to be whites and free persons of colour, more than 3000 free blacks, and above 70,000 slaves. Bourbon is divided into eleven parishes. St Denis is the capital of the island, and the residence of the governor; but in the number of its houses it merits no higher distinction than that of a village. Similar villages are set down in other parts of the island. The trade of Bourbon is carried on with Mauritius and Madagascar, the other islands in the Indian ocean, and the settlements on the eastern coast of Africa, and consists chiefly in bartering the productions of the island for those commodities which are in demand among the inhabitants. Its connection with Europe must also be noticed as a source of commercial intercourse.

The isle of Bourbon, when first discovered in 1545 by a Portuguese navigator, was destitute of inhabitants; and 100 years nearly elapsed, when the governor of the French settlement at Madagascar transported, in 1642, twelve malefactors who were condemned to perpetual exile. In 1654, a few Frenchmen, with some negroes, formed a settlement on its shores, and gave it the name of Bourbon; but the failure of their crops from hurricanes, and the hardships and privations to which they were exposed, forced them to abandon their possessions, and embark with their whole property for Madras. The remains of the French settlement in Madagascar, which escaped the massacre of the natives, escaped to Bourbon, and, with the crew of a privateer which had been wrecked on the coast, formed a new establishment. The colony, rising in prosperity and wealth, was claimed by the French East India Company as their property; various disputes took place between the colonial government and the inhabitants; and it was not till 1735, when the prudence and moderation of the governor restored it to order and tranquillity. The mad spirit of the French revolution reached this distant settlement. The decree of the Directory for the emancipation of the negroes and the abolition of slavery, had it been put into execution, would have proved its ruin; but it was wisely opposed by the inhabitants. Bourbon came under the dominion of Great Britain in 1810.

BOURBON LAKE, a spacious lake of North America, which derived its name from some French traders, is about 18 miles in length, and is nearly circular; the surrounding territory is mountainous, or composed of barren plains and extensive morasses; cedar, spruce, and maple trees, are found in the forests; and all kinds of foxes are abundant on its borders, which, from the severity of the climate, is sparingly visited by any other description of animals.

BOURBONNOIS, a former province of France, which is now included in the department of Allier; enjoys a mild and agreeable temperature; is in some places covered with extensive forests; abounds with vineyards; produces corn, hemp, and fruit in abundance, and affords excellent pasturage for cattle. Numerous mineral springs, both hot and cold, are found in the province; and mines of iron and coal are wrought in different places. The Loire and the Allier are the principal rivers, and the chief town is Moulins.

BOURDEAUX, one of the most ancient and celebrated cities of France, and capital of the department of the Gironde; stands on the west bank of the river Garonne, and at the distance of forty miles from its junction with the sea. Bourdeaux was a place of considerable importance in the time of the Romans, and perhaps is indebted for its origin to a colony of that people. Some magnificent remains still exist to attest its former grandeur. The Goths became its masters in the fifth century, and it afterwards suffered severely from the ravages of the Normans; for nearly three centuries it remained in the possession of the English; and after its reunion with France it became the scene of many disastrous occurrences, first, during an insurrection excited by the oppressive exactions of a salt tax, and afterwards during the civil wars in the time of Henry IV.

The modern form of Bourdeaux is that of a crescent; it is surrounded by a wall, and defended by three forts. Many of the new streets are built on a regular and elegant plan; some of the public edifices are conspicuous for their grandeur, and the theatre is particularly specified as one of the most magnificent structures of the kind in Europe. A corn-mill, the machinery of which is driven by the tide, conducted to it by canals, is a huge building, erected by a public company, at an expence of L.350,000. Beside a cathedral and numerous churches, Bourdeaux has an academy for promoting the improvement of the fine arts, which was established in 1712, and the university was founded in 1441.

The population of Bourdeaux is stated at 100,000, part of whom is occupied in the manufacture of serge, printed calicoes, stockings, pottery, glass, and cordage; but its chief prosperity depends on extensive commerce, of which the whale and cod fishery form a considerable branch. Four or five hundred ships are sometimes seen in its spacious harbour at one time, taking on board wine, brandy, vinegar, various kinds of fruit, turpentine, corkwood, honey, olives, and anchovies, in exchange for woollen-stuffs, tin, copper, lead, coals, herrings, leather, butter, cheese, salted beef, &c. Bourdeaux is 270 miles distant from Paris, and 70 miles from Rochelle.

BOURGES, an ancient town of France, is the capital of the department of Cher, and stands on the Erve, at its junction with the Eure, was established in the end of the fifteenth century as a commodious station for internal commerce, but the scheme was frustrated by a dreadful conflagration, in which more than 7000 houses were destroyed; is now chiefly remarkable for its cathedral, a splendid Gothic edifice, and a few manufactures of woollen stuffs, linens, and stockings, which afford employment to a small portion of its inhabitants, amounting to about 15,000.

BOW, an offensive weapon, constructed of wood, horn, steel, or other elastic materials, for the purpose of projecting an arrow. The bow and arrow form the most ancient and most universally employed warlike instrument. See ARCHERY.

BOYAR, a title applied to the Russian nobility, and limited, it is supposed, to those of the higher order.

BOYER, ABEL, author of a well known dictionary of the French language, was born at Castres in France in 1664; was driven from his native country in consequence of the revocation of the edict of Nantz, settled first at Geneva, and remained some time in the prosecution of his studies at Franeker, and finally fixed his residence in England, where he was employed in superintending a newspaper, and in conducting various periodical publications. He was the author of a life of queen Anne, and was so much a master of the English language as to produce an imitation of one of Racine's tragedies, which was represented on the stage; but he is best known as the author of a grammar and dictionary of the French language, which are still regarded as valuable works.

BOYLE, ROBERT, an eminent philosopher, was the seventh son, and the fourteenth child of Richard, earl of Cork, and was born at Lismore, in Ireland, in 1627. Descended from a noble family, not less distinguished by mental endowments than by their influence in public affairs, he inherited from it no small portion of intellectual talent. His early education was conducted in his father's house; he spent several years at Eton, afterwards visited the continent, and during his residence at Geneva assiduously devoted himself to the acquisition of mathematical and physical science, as well as to the improvement of his knowledge in modern languages.

The death of his father, which happened before he reached England, left him in possession of an estate in England, and a considerable property in Ireland; and from this time he seems to have determined to live in philosophical retirement. He was one of the first members of the small, but learned body, which held private meetings, first at Oxford, and afterwards in London, for the purpose of investigating subjects of natural philosophy by experimental inquiry, and who styled themselves the *Philosophical College*, which, after the restoration, was incorporated, in 1663, under the name of the "Royal Society." Before this time Mr Boyle had published various tracts relative to chemistry and different departments of mechanical philosophy; and, with the assistance of Mr Robert Hook, he afterwards made considerable improvements in the construction of the air-pump, and published the result of his experiments on the elasticity of the air.

In the year 1668 he removed to London, and fixed his final residence in the house of his sister, lady Ranelagh, with whom he chiefly lived during the long period of forty-seven years. Mr Boyle was held in high respect by the king; he had been solicited to enter into the clerical profession, with the view of being promoted to the highest rank; he was appointed to the provostship of Eton college, and he was elected president of the Royal society; but all these honours he declined, probably from his reserved and modest manner, as much as from other causes which have been assigned by his biographers. His constitution had been always feeble, and the attention which his health required may excite surprise that he was able to undergo so much labour in his numerous literary pursuits; but he seems to have adjusted the occupation of his time with great order and economy. Having survived his sister one week, he died in the end of December 1691, in his 65th year, and his funeral sermon was preached by the celebrated bishop Burnet.

Mr Boyle is to be regarded as one of the revivers of physical science, to the progress of which the ingenious experiments which he instituted, and the various instruments which he invented or improved, in no small degree contributed. He was no less distinguished by his piety and zeal in the service of religion; his benevolence was liberal and active, and his character was adorned with every other amiable and social virtue.

BRABANT, a district of the Netherlands, which, in various periods of its history, has been distinguished by the title of duchy and province, more lately formed some of the departments of France, and finally a part of the kingdom of Belgium. Holland, Guelderland, and Liege are its boundaries on the north and east, Namur and Hainault are on the south, and Flanders and Zealand on the west. The circumference is estimated at 140 miles; and having been often the scene of active warfare, it includes many fortified towns, and a great number of populous villages. Brabant was formerly divided into four quarters or districts, Louvain, Brussels, Antwerp, and Bois-le-Duc. It is watered by some large rivers, as the Meuse, the Scheldt, the Dyle, beside some smaller streams; and it is traversed by canals, which greatly facilitate the commercial intercourse of the country. The soil is fertile, and agriculture is in a state of great improvement. The manufactures of lace and various kinds of woollen stuffs, have been long prosperous.

BRABEJUM, AFRICAN ALMOND, a genus of plants belonging to the class Polygamia.

BRACCIOLINI, POGGIO, an eminent scholar who flourished in the fifteenth century, and contributed greatly to the restoration of literature; he was a native of the Florentine republic, and was born in 1380, at a time when Florence had become the resort of learned men,—when the liberal arts were patronized and encouraged,—and when the writings of Petrarch and Boccacio, being generally read, refined and improved the public taste. To several learned men who were attracted to this seat of learning and the fine arts, Poggio was indebted for a great share of the profound knowledge which he attained of the Greek and Roman classics. In his twenty-second year he visited Rome, and was appointed to an official situation under the Pope; and with some intervals of absence, when the court of the Vatican was disturbed with domestic dissensions or harassed with foreign wars, he continued in the service of successive Roman pontiffs for the long period of half a century. In the latter years of his life he was promoted to the chancellorship of the Tuscan republic; and when he arrived in Florence, he was honoured by his fellow citizens with other essential marks of their esteem and regard.

After his death, which happened in 1549, his portrait was exhibited in the public hall, and a statue was erected to his memory.

But the labours of Bracciolini in preserving the numerous relics of ancient literature from oblivion, entitle him to the highest praise. By his industry a complete copy of Quintilian's works was presented to the public; he recovered several books of the Argonautics of Valerius Flaccus; some of the orations of Cicero; some of the comedies of Plautus; the fifteenth book of Petronius' Arbiter; and, with the assistance of other learned men, the works of Lucretius, Silius Italicus, Tertullian, Columella, and other ancient writers. He was the author of various works, some of which are of a moral and instructive nature, and others are written in a satirical strain; they are chiefly in the form of dialogue. But the reader who wishes for a full detail of the life of this eminent scholar, and to be gratified with a comprehensive view of the literature of the age in which he lived, may consult with advantage Shepherd's *Life of Poggio*.

BRACHMANS, Brachmins, or Brahmins, the chief of the four casts or tribes into which the native Hindoos, from time immemorial, have been divided. The Brahmins of modern times are supposed to be descended from the ancient gymnosophists or philosophers of India, whom the Greek sages visited, and from whom they were desirous of learning wisdom; and it seems probable that some of the peculiarities of the celebrated doctrines of Pythagoras were derived from the same source. The knowledge of astronomy was early cultivated by the Brahmins, and the astronomical tables which have been ascribed to them are supposed to be of considerable antiquity; but the Brahmins of the present day have no pretensions to scientific attainments; the extent of their learning is limited to metaphysical speculations. To them alone the functions of the priesthood are intrusted; and the highest respect and veneration are paid to their persons by the other casts or tribes of the Hindoos.

BRADFORD, a town of Wiltshire in England, which is finely situated on the declivity of a hill on the banks of the Avon; and, with a population of between seven and 8000, has been long famous for its extensive manufactories of superfine broad cloth.

BRADFORD, a manufacturing town in the westriding of Yorkshire in England. Various kinds of woollen stuffs, wool-cards, combs, and leather boxes, and three iron founderies, afford the chief employment to the inhabitants, who exceed 6000. The abundance of iron ore and coal in the vicinity, and the advantage of inland navigation, contribute to the prosperity of the manufactures and trade of Bradford. In a large public hall the various productions of its manufactures are exhibited for sale.

BRADLEY, Dr James, an eminent English astronomer, was born at Shireborn in Gloucestershire, in 1692, passed through the elementary part of his education at a boarding school in North Leach, and, being destined for the clerical profession, was admitted as a student at Oxford in 1711. He took orders in 1719, and was presented to a living in Herefordshire. His inclination to astronomical pursuits appeared early, and was encouraged by the kindred zeal for the same science of his uncle Dr Pound, with whom he resided for some time as curate at his living of Wanstead in Essex. In 1721, he was appointed Savilian professor of astronomy in the university of Oxford, in consequence of the death of the celebrated Dr Keill, and thus became the associate and friend of the illustrious Dr Halley, who was then Savilian professor of mathematics. He assiduously devoted himself to the cultivation of astronomical science, and the result of his observations was occasionally presented to the Royal society. In 1725, when his attention was directed to the parallax of the fixed stars, he was led to the discovery of the aberration of the celestial bodies, and the nutation of the earth's axis. These splendid discoveries, of which an account appeared in the Transactions of the Royal Society for 1728, spread his fame as a philosopher wherever science was known and cherished. In 1730, he was appointed lecturer in astronomy and experimental philosophy; and, in 1742, he succeeded Dr Halley as astronomer royal at Greenwich. This situation afforded him a fine opportunity of exercising his diligence and accuracy in conducting astronomical observations. He furnished the observatory with the best instruments, in which he liberally acknowledges the aid which he derived from Mr Graham and Mr Bird, who were employed in their construction; and he discharged his duties during the last twenty years of his life in a manner not less creditable to himself than beneficial to the world, in the practical application of his observations and discoveries. But it is melancholy to record, that a depression of spirits, accompanied with an apprehension of mental derangement, embittered the close of his life. He died in 1762, and in the 70th year of his age.

BRAGA, a city of Portugal, and capital of the province of Entro Douro-e-Minho, stands in a spacious valley of the same name on the river Cavado. The remains of an aquæduct, of an amphitheatre, and the discovery of coins, furnish evidence of the importance of this place in the time of the Romans. The streets are broad, light, and open, but the houses in general are small. The cathedral is a large Gothic structure; and a church and monastery, placed on an elevated situation, form a fine object, and terminate the view from one of the streets. Braga has declined from its former prosperity; but it has still a considerable manufactory for common hats. The population is stated at 13,000.

BRAGANZA, a town in the province of Tralos-Montes in Portugal, stands on a spacious plain on the borders of Leon and Gallicia. It is defended with a castle and towers. The population is about 3000; and velvet and some other silk stuffs are its only manufactures.

BRAHE, Tycho, a celebrated astronomer, who was born at Knudstorp in Shonen in Norway, and was descended from an illustrious Swedish family. He was destined by his friends for the profession of the law; but a passion for astronomy began to discover itself in his 14th year; and the remarkable coincidence between the calculations of a solar eclipse and the time of its taking place in 1560, made such an impression on his mind that he resolved to prosecute a science which depended on such certain principles. Having finished his studies at Copenhagen, he visited the principal cities of Germany and Italy, and became acquainted with the chief astronomers of the age. On his return to Copenhagen his reputation as an astronomer reached the court, to which he was invited; and the discovery of the new star in the constellation Cassiopeia, which appeared in 1572, confirmed the opinion which had been held of his talents and industry. Frederick, king of Denmark, being informed of the astronomer's intention of removing to Basle, in Switzerland, for the purpose of carrying on observations, generously provided for him one of the most liberal establishments which any monarch has erected for the benefit of science. The island of Huen was assigned to him, a splendid observatory was built, and well furnished with instruments, and a pension for his support was granted. The expence of this celebrated observatory, which was called *Uraniburg*, amounted, it is said, to the sum of L.20,000. In this situation he lived twenty-one years, and was frequently visited in his scientific retreat by persons of the first rank and highest reputation. Even crowned heads condescended to visit the astronomer, and among others James VI. of Scotland, when he visited Copenhagen in 1590, at the time of his marriage with Anne of Denmark, spent eight days with Tycho at Uraniburg. But the death of his munificent patron was fatal to the astronomer; by the advice of wicked ministers the young king was persuaded to discontinue his pension, and he was forced to abandon his favourite retreat, and to seek an asylum in a foreign land. He removed his family, his books, and instruments to Rostoch, where he experienced the liberality of the emperor Rodolph II. who granted him a handsome pension, and erected an observatory for his use in the vicinity of Prague. But his mind was broken with disappointment, which scarcely ever permitted him to resume his labours in his new situation with his former zeal and industry; and a severe disorder terminated his existence in 1601, when he had reached the 55th year of his age. It has excited just surprise that Tycho, who was preceded by Copernicus, should not have adopted the system of the universe proposed by that philosopher, or rather that he should have contrived another, in which he supposes the earth to be placed in the centre, and the sun, with all the planets, performing their revolutions round it; but it has been alleged that he was influenced by a spirit of opposition, or by the vanity of being the author of a new system, which from him received the name of *Tychonic*. His fondness for the study of alchymy and judicial astrology is less to be wondered at. The rays of science had scarcely begun to penetrate the dark cloud which yet hung over the human intellect.

BRAHMAPOOTRA, the largest river of India, the sources of which have remained hitherto unexplored by Europeans; but it is supposed they are not far distant from those of the Ganges, from which they are separated by a snow-covered mountainous ridge, about the 32° of north latitude. Proceeding in its course eastward, the Brahmapootra traverses the country of Tibet, where it is known by the name of Sanpoo, passes to the north of Teshoo-Loomboo, the residence of Teshoo Lama, and thence flows in a wide extended bed through numerous channels, and forming many islands. Swelled by many tributary streams, it penetrates the frontier mountains of Tibet, takes a vast circuit towards the Chinese empire, and, by a sudden change of its course, runs westward, through Assam, where it receives an immense accession to the body of its waters. Entering Bengal, it makes a circuit round the western point of the Garrow mountains, and again changing its course in the province of Dacca, is joined by the Megna, a river of smaller size, which gives its name to the united streams, till they mix their waters with the Ganges, near the bay of Bengal. The whole course of the Brahmapootra, including its various windings, is supposed not to be less than 1650 miles; in its course of 400 miles through Bengal it greatly resembles the Ganges in its general character, and during the last 60 miles, while it bears the name of Megna, it forms a stream from four to five miles in breadth.

The united waters of the Ganges and Brahmapootra, below Luckipoor, form a capacious gulph, studded with islands, some of which are of considerable magnitude. The sudden influx of the tide, which is known by the name of *Bore*, prevails in the principal branches of the Ganges and the Megna; but the Hooghly river, and the passages between the islands and sands in the gulph which is formed by the confluence of the Brahmapootra and Ganges, are most subject to this extraordinary influx of the ocean.

BRAINTREE, a town of Essex, in England, which seems to be a place of considerable antiquity; the streets are narrow, and many of the houses are constructed of wood. The population is about 3000, and, with the village of Bocking, which forms part of the town, the whole number of inhabitants is about 6000, many of whom are engaged in the manufacture of baize, which was introduced by the Flemings, who were driven from the Netherlands by the oppressions of the Duke of Alva.

BRANDENBURG, MARQUISATE OF, a country of Germany, which extends about 200 miles from east to west, and more than 100 miles in breadth from north to south; is bounded on the north and east by Mecklenburg, Pomerania, and Poland; and on the the south and west by Lower Lusatia and Saxony, the duchies of Madgeburg and Lunenburg. The Elbe and the Oder, with their tributary streams, are the principal rivers which traverse the territory of Brandenburg. A great proportion of the soil is light and sandy; but by industry and judicious improvement it produces abundant crops of every kind of grain. The rearing of cattle and sheep is a great object of attention in the rural economy of this province. The breed of sheep has been greatly improved, with the view of obtaining a finer wool, to furnish materials for the manufactures of the country. Wood is abundant, and not only affords an ample supply of fuel for domestic use and manufactures, but for ship-building and exportation.

The revocation of the edict of Nantz, was peculiarly favourable to the manufactures and commerce of this province. Twenty thousand French refugees, driven from their own country, settled within its territories, and established various manufactures, which have continued to prosper to the present day. The internal commerce of the country is greatly facilitated by various canals, which form communications between the towns and its navigable rivers.

The population of Brandenburg exceeds 750,000. The Lutheran form of religion prevails generally among the inhabitants, but many, especially on the coast, profess the Calvinistic faith; and the number of Roman catholics is considerable. Full liberty of conscience is permitted to all classes. Berlin, Brandenburg, and Potsdam, are the principal towns.

The family of Brandenburg is of great antiquity, founded, according to some historians, by the Sclavonians, who distinguished it by the name of the *Guards of the forests.* The title of Marquis was conferred in the beginning of the 10th century, and having passed through various families it came into the possession of Frederick the VI. of Nuremberg, who was dignified with the title of elector and archchamberlain of the holy Roman empire. Brandenburg was long subject to Poland, and each succeeding margrave received investiture of Prussia from the Polish kings. In consequence of a treaty with the king of Poland, Frederick William was acknowledged to be sovereign of Ducal Prussia, in an assembly of the states at Konigsburg in 1663; by the treaty of Vienna the emperor confirmed this title, and Frederick his son was proclaimed king of Prussia in 1701. His grandson, the great Frederick, succeeded to the crown, and astonished Europe by his brilliant victories, and the extraordinary success of his arms.

BRANDENBURG, the capital of the Marquisate of the same name, stands on the banks of the Havel, by which it is traversed, and divided into the old and new town. The fishery in the rivers and lakes in the neighbourhood is a beneficial concern; hops and vines are extensively cultivated; the manufactures of woollen stuffs, linen, and fustians, established by the French refugees, still flourish; and the commerce, to which the inland navigation greatly contributes, is considerable.

BRANDY, a spirituous liquor, which is obtained by the distillation of wines. See CHEMISTRY.

BRASIL, an extensive region of South America, reaching from the north side of the equator to the 34th degree of south latitude, and stretching into the interior almost to the 70th degree of west longitude; is bounded on the north by Guiana and the Atlantic ocean; by the same ocean throughout the whole extent of its eastern border; and on the south and west by Paraguay, and vast tracts of country hitherto unexplored.

External aspect.—The descriptions of navigators and travellers represent the appearance of Brasil from the coast as extremely rich and beautiful. Blessed with a serene and salubrious atmosphere, its surface is finely diversified, and its soil exuberantly fertile; it abounds with trees which are green with eternal foliage, and loaded with delicious fruits, which distil precious gums, and diffuse an exquisite fragrance. Much of its interior is still unknown; but the curiosity or avarice of adventurers has led them to trace the course of some of its largest rivers, to scale the summit of its loftiest mountains, to traverse some of its most spacious savannahs, and to penetrate its gloomiest forests; and they have spoken with admiration of all these objects, of the infinite variety, as well as of the inestimable value of its indigenous plants, of the singular form and strange nature of many of its native animals, and of the degraded condition and the horrid customs of some of the human tribes who claim it as their country.

Climate.—Though a large portion of Brasil be exposed to the rays of a vertical sun, yet it is not, like Africa, parched with a withering influence, but is fanned with a perpetual breeze, which maintains a most refreshing and invigorating coolness of temperature. The sea-breeze begins to blow about nine o'clock in the morning, and continues till towards midnight, bracing the nerves, and preventing or removing languor and lassitude. When it subsides, about half an hour of sultry calmness intervenes, but the uneasiness which it occasions is speedily dissipated by the land-breeze, which prevails till morning. The transition from light to darkness is so sudden that, on the setting of the sun, the twilight is scarcely perceptible; but the nights are, in general, so mild and salubrious that they may be safely and pleasantly spent in the open air. As in other tropical latitudes, the year in Brasil is divided into the rainy and the dry seasons. Before the fall of rain the breeze is suspended, the weather becomes oppressively sultry, dense and dark clouds are quickly collected, and in awful stillness brood over the country, and then "the rain descends and the floods come." The rain called "the first waters," falls near the beginning of the year, and continues about three weeks; the weather then clears up till about May, and from that time till near the end of September the "second waters" fall in torrents, causing the rivers to overflow their banks, and making all the level lands assume the appearance of immense inland seas. But the return of the dry season speedily removes this excessive moisture, and frequently brings about an opposite extreme. For during the dry season the waters not only subside from the land, but many of the rivers are also deprived of their streams; and if the rain happen to be long delayed beyond its usual time, or to fall in insufficient quantity, famine, with all its horrors, is the sure and calamitous consequence. When this takes place, as was the case in the years 1791-2-3, whole provinces are depopulated. If, however, the inhabitants were sufficiently acquainted with the climate of their country, they would be enabled to avail themselves of its fertility, so as to lay up a store of provisions both for themselves and their cattle, and to form reservoirs amid its rocky recesses large enough to contain a supply of water during the most excessive and the longest continued droughts.

Mountains.—Of the direction, the structure, and the elevation of the mountainous ranges which traverse Brasil, little is accurately known. A lateral branch of the Andes proceeds towards the east; and from this central and lofty range, numerous chains diverge in opposite directions. Of these chains the Serra des Emeraldas, and the Serra do Frio, are prolonged towards the south, while that branch called

Matto Grosso and others stretch towards the north. The mountains of the Serra de Ibiapaba extend, says Southey, about eighty leagues in length and twenty in breadth; they rise in waves, one towering above another; their sides are in some places rocky, in others clothed with verdure. To ascend them is the hard labour of four hours, in which hands and knees, as well as feet, must frequently be exerted; but, having gained the summit, the traveller is in a region which is diversified with every beauty; he beholds rocks, peaks, hills, and vallies, woods and wide savannahs, clouds below hanging over the flat country, and ocean in the distance. The days are short, the morning being always cloudy, and the evening hastened by the mountains on the western side which overtop the others. The greater part of the coast of this country is walled by a mountainous barrier, rocky and picturesque; and in some places, as at Rio Janeiro, exhibits a bold and precipitous front, and in others, as at Pernambuco, ascends in a series of broad, level, and fertile terraces.

Rivers.—The natural boundaries of Brasil on the south and the north are formed by two of the largest rivers in the world. The Rio de la Plata, on the south, belongs indeed more to Spanish than to Portuguese America; but as its majestic grandeur depends in a great degree on the waters which flow into it from the country claimed by this latter people, it deserves particular notice in the most partial enumeration of its streams, the principal of which are the Paraguay, the Parana, and the Uraguay, which drain the southern regions of Brasil, and swell the mighty waters of La Plata. The still more magnificent river which flows along the northern frontier of Brasil is known by several names. It has been called the Amazons river, from a nation of female warriors supposed to inhabit its banks; but with more propriety, as well as justice, it has been denominated the Orellana river, to commemorate the name of that enterprizing European who first traced its course from the confines of Peru to the Atlantic ocean. This river, by far the greatest in the known world, rises among the stupendous Andes, and winds its way to the ocean through regions diversified by every variety of soil and surface. The length of its course, which is chiefly in a north-eastern direction, is said to be 3300 miles, and its breadth, directly under the line, where it falls into the Atlantic, about 150 miles. It contains innumerable islands, some of which are sufficiently extensive and populous to constitute kingdoms. The number of its tributary streams is above 200; and some of them are said to exceed the Danube or the Nile in the length of their course and the volume of their waters. Of these the Parima, the Negro, the Yupara, flow into it from the north; while the Paras, the Madera, the Parapatinga, the Tocantin, with its western branch the Araguay, traversing the northern provinces of Brasil, hasten towards it from the south. Besides these immense rivers, the coast of this country is indented by the mouths of a multitude of others, which flow from mountains at no great distance inland. The greatest of these is the Rio Francisco, between the provinces of Bahia and Pernambuco; the Maranham, the Jaguribe, the Rio Grande, the Rio Dolce, and many more of these streams which throughout the coast fall into the Atlantic, would, in most other countries, be regarded as magnificent rivers.

Mineralogy.—The mountains of Brasil belong to the primitive class of rocks. The peaks and mural masses are chiefly composed of granite or of syenite, while argillaceous schistus and some of its associates skirt the declivities. The sand, fragments, and rolled masses of rocks, bear strong indications of their metalliferous nature, and that they are the repositories of beds and veins of iron, copper, tin, and other metals; but the gold and the diamonds which have been found in the alluvial depositions of this country have inspired an avidity, and led to pursuits hostile to the examination of the mountains with the view of ascertaining their nature or disclosing their treasures. These,—the most precious of the metals, and of the gems which, from the beginning, were eagerly sought after,—have long been found in considerable abundance in the deep soil of some of the vallies, and in the banks and beds of the rivers; and, from this search, some derive riches, and many procure a livelihood.

Vegetable productions.—A complete enumeration of the plants of a country clothed with everlasting verdure, and covered with forests of boundless extent, is a task which has not hitherto been executed, and which indeed is scarcely to be expected. The cotton-shrub and the sugar-cane are extensively cultivated; the forests supply timber in the greatest abundance and richest variety for all the purposes of the ship-builder, the house-carpenter, the machine, and the cabinet-maker; Brasil wood, which, from its abundance, has imposed its name on the whole region, fustic and other woods in demand by the dyers, because of their colorific qualities, grow wild among the mountains. Palm trees in all their gradations of species and variety are met with every where, displaying at once their opening blossoms and their mature fruit. But these, with all their grandeur and beauty, are far excelled by the Acayba, with which whole tracts of the Brazilian coast are covered. It is delightful, says Vasconcellos, to behold its pomp when it is re-clothing itself in July and August with the bright verdure of its leaves; when, during our European autumn, it is covered with white and rosy tinged blossoms; and when, in the three following months, it is enriched with its fruit as with pendent jewels. Its leaves have an aromatic odour; its flowers are exquisitely fragrant; its shade is deep and delightful; a gum equal to that of Senegal exudes from it in great abundance; its fruit resembles a pear, at the end of which grows a kidney-shaped seed, known in England by the name of the cashew-nut. Every part of this admirable tree is appropriated to some useful purpose. The juice of the fruit produces a species of wine, the pulp an excellent flour; the wood may be used for any purpose which requires durable or beautiful timber; the outer bark yields a black, and the inner a yellow dye; the gum is medicinal. Manioc, maize, kidney beans, wheat, rice, &c. are cultivated for food. The manioc, a plant peculiar to this country, has a root resembling our parsnip, which is variously prepared and eaten by all classes of the country. Thirty-three species of it have been distinguished. The shrub which produces this root rises to the height of six or seven feet; it has a knotted stem, small branches, clusters of oblong leaves, and pale yellow flowers. Various sorts of spices, ipecacuanha, and other drugs, tobacco, coffee, and indigo, grow in Brasil, and are thence exported to other countries. European vegetables in all their variety are cultivated, and grow luxuriantly in the Brasilian gardens.

Animals.—But this country has deservedly been as far famed for its animal as for its vegetable productions. It abounds with birds of the most splendid plumage, among which the different varieties of parrots and humming-birds are conspicuous. The herds of horned cattle are in some places so numerous as to be hunted merely for the sake of their skins. Horses, unaccustomed to the yoke, scour the country in thousands. Wild beasts, such as boars, leopards, ounces, and the still more tremendous jaguar, the Brasilian tiger, lurk and range in the forests. Apes and monkeys of all kinds and colours, an extraordinary species of porcupine covered with long spikes instead of quills, the armadillo, or shield-hog, and many more of the same description, are often thought too common. Serpents from a few inches in length to the most enormous size, scorpions, vampire bats, large frogs, and spiders, and immense colonies of ants, are justly deemed the plagues of Brasil, and frequently, especially the last, greatly injure the plantations, gardens, and houses. It need scarcely be added to this enumeration, that the sea-coast, the lakes, and the rivers of this country teem with many sorts of fishes. The oyster-shells are so large that they are converted into culinary vessels and water basons, and entire hills of them are to be found piled up on the shores.

Inhabitants.—The population of Brasil consists of aboriginal Indians, either in a wild or domesticated state; of Brasilians, or the descendants of European settlers; of Mamaluccos, or the mixed cast between the European and the Indian; of Mulattos, or the mixed cast between the European and the African; of Mestizos, or the mixed cast between the Indian and the African; of negroes imported from Africa in a state of slavery; and of Europeans who have lately emigrated from their native country. These various classes are distinguished not only by their external appearance, but also by other characteristic features.

Aboriginal tribes.—The native Indians of Brasil are comprehended in three distinct tribes or nations,—the Tapuyas, the Aymores, and the Tupis. On the discovery of this country the Tapuyas were found in possession of the northern side of it, from the shore backward into the interior, as far as it could be explored. The Tapuyas are represented as the least cruel of all the savage race to which they belong; they are cannibals, but they eat not their enemies, but their own dead, as the last demonstration of their affection. The chief is distinguished by a crown tuft of hair, and long nails. They frequently change their dwellings; they live by hunting and fishing, and bake their meat in an earthen oven lined with leaves. It is the privilege of the male sex to be beautified, and during their boyhood their ears, to this end, are bored and stretched, and the under lip is cut through parallel with the mouth. When they are about to marry, to complete their charms large holes are bored in their cheeks. The Aymores are far more degraded. They are an inland tribe; for when they came to the coast they could not swim, and a river was a sufficient defence against their terrible attacks. Their language is unusually harsh and guttural. They have neither garments nor habitations—naked as beasts, they lie down like beasts in the woods, and like beasts can run upon hands and feet through thickets where it is impossible to follow them. They feed on wild fruits, and what they kill in the chase or in battle. So impatient are they of slavery, that when taken by the Portuguese, they have refused food so resolutely as to die of hunger. The Tupis or Tupinambos inhabit the southern provinces of Brasil. In their language there is neither f, l, nor r; a defect which has given rise to the jest, that these savages have neither (fey, ley, nor rey) faith, law, nor royalty among them. Their names for the numerals did not extend beyond five when first visited by the Portugueze. By the term *Jupa*, they express father, supreme being, and thunder. Yet to this *Jupa* or *Supreme Father*, they addressed no prayers; but disasters, dreams, shadows, nightmare, generated a superstition which the Payes, at once quacks, jugglers, and priests, took care to strengthen. Each Paye lived in a dark hut, into which none dared to enter. It was a deadly sin for any man to refuse his daughter, or any thing else, to these Payes, and none ventured to incur the guilt. The macara, a kind of wooden rattles, form the only object of their worship. The Tupinambos live in villages surrounded by a close palisado, in which are loopholes for their arrows. At the entrance a few heads are stuck up on pikes to awe their enemies. The houses within this inclosure may not exceed six or seven; but they are about 150 feet in length, and contain 20 or 30 families. A warlike expedition is preceded by many ceremonies. On these occasions an old orator exclaims—" What! Tupinambos, is this the example our fathers have left us, that we should thus waste our days at home in idleness. They went out, and conquered, and devoured; and shall the enemies who durst not stand in their sight, come to our doors and bring the war home to us? No, my countrymen, let us go out, and kill, and eat!" The Payes go round the settlements and tell them, speaking through the macara, that their gods delight to be satisfied with the blood of their enemies. The men, boys, and women, in separate companies, set up a most hideous howling; then the Payes rattle the macara, and blow the smoke of petum on the men, saying, receive the spirit of courage that ye may conquer your enemies. A club is their principal weapon; it is made of the iron-wood of Brasil, from five to six feet long, with a thin circular-shaped head sharpened to an edge, so that it becomes a tremendous battle-axe. They have also bows and arrows, and are unerring archers. When they approach the enemy they hold up their fifes of human bone, and rattle their necklaces of human teeth. When a prisoner is brought home, he is forced to cry out to the women, *Here am I come to be your meat!* Then he is for a while pelted and pulled and tormented by the women and children; afterwards he is led into the area and nearly strangled; then strings of macara, or rattles of divination, are fixed about his legs; and in this state he is made to dance what is called the *aprasse*. When they have gone through the routine of these and similar ceremonies, the prisoner's brains are knocked out with one blow, his body cut in pieces, and laid on the boucan to be broiled. The boucan is a wooden frame, made of four stakes driven into the ground, and sticks laid across; food thus smoked and dried is said to be *buccaneered;* and hence the origin of the name of that extraordinary race of pirates, so long the scourge of South America. On the birth of a child the father takes to his hammock, and is nursed with care; lest from the intimate union which is supposed to subsist between him and his offspring the child should suffer. No man marries till he has taken an enemy, nor is suffered to partake of a drinking feast while he remains single. The women are fond of long hair, and paint their cheeks red, and blue, and yellow. When the country was first discovered they could spin and weave cotton; they cultivated manioc and maize, and were skilful potters. They were also excellent fishers, and preserved their fish by drying it on the boucan, and then reducing it to powder. The labours of the Jesuits introduced many salutary changes among this race; and, for the sake of farther improvement, the extinction of the order is a subject of regret.

Negro slaves.—In Brasil, the loss of liberty is greatly mitigated by many privileges not generally enjoyed by African bondmen. The laws allow them the Sabbath, and thirty holidays in the course of the year, and compel the master to manumit his slave on the payment of the purchase-money; a woman who has reared ten children is entitled to her freedom; if the sum of five pounds is offered at the baptismal font, the master must manumit the child. Many slaves obtain their liberty on the death of their masters; and many humane planters gratify their feelings by exercising this mode of charity during their lives. The inhabitants of Maranham and Para have the character of treating their negroes more rigorously than the other inhabitants of Brasil, and refractory slaves are sold to this worse slavery from Pernambuco. Nothing tends so much to keep a slave in awe as the threat of sending him to Maranham or Para.

Brasilians.—The descendants of the Portuguese adventurers, convicts and prostitutes, by whom this country was first colonized, are known by the distinctive appellation of Brasilians, and are different in their character as they inhabit the town or the country. The merchants have little intercourse; the planters are more social; the priesthood is sadly degraded. The females are frank in their manners, lively and entertaining in their conversation; they have generally black eyes and good features. Exclusive of their colour, finer specimens of the human form cannot be found than what is exhibited by the mulatto females. In gay families, cards and backgammon are introduced in the morning, and continue the whole day. Knives and forks are seldom seen at entertainments; their office being in most cases performed by the fingers. But Brasil is rapidly emerging from this state of semi-barbarism. The inhabitants of the interior are called Sertanejos. They live in mud-cottages, and have hammocks instead of beds, and sometimes instead of chairs. Children run about naked as they were born, and grown persons are but scantily clothed. At home the men wear a shirt and drawers; abroad, a jacket and pantaloons made of leather. The women are content with a shift and petticoat; they never wear stockings, and seldom shoes. The Sertanejos are employed chiefly in the rearing of cattle, which at certain seasons they bring to the towns. They live mostly on flesh, which they eat three times a-day; they are said to be an ignorant, superstitious, and revengeful race.

Cities.—Brasil contains a great number of large and populous cities. St Sebastian, the capital, stands on an eminence close by the magnificent bay of Rio Janeiro. The entrance into this bay is through an opening in the ledge of rocks which separates it from the sea. Within this natural barrier stretches an extensive bay surrounded by an amphitheatre of lofty mountains, exhibiting huge columnar masses of granite, and covered with trees of unfading foliage. Amid this sublime scenery the city of St Sebastian is built of stones from the neighbouring rocks in straight, parallel, and intersecting streets. The palace, the mint, and public halls, form a spacious square. The hills behind are covered with woods, gardens, houses, convents, and churches. This city lies in 22° 50′ S. lat. and is said to contain 60,000 inhabitants. St Salvador, the capital of the province of Bahia, is built on All Saints bay, which is of still greater extent than that of Rio Janeiro. The entrance is three leagues wide; it is entered from the south, having the continent on the right hand, and the island Itaparica on the left. The bay extends a whole degree west and north; it receives many rivers; its water is every where deep, and its surface is studded with islands. This magnificent bay, with its creeks and coves, is denominated the Reconave. On the south side of this bay, St Salvador, the former capital of Brasil, is built, remarkable neither for elegance nor cleanliness, but a place of great trade, and consequently of great population. The next in magnitude of the Brasilian cities is St Antonio de Recefe, so called from a singular reef of rocks interposed between the harbour and the ocean. This town, the capital of Pernambuco, consists of houses two, three, and even five stories high. The houses are of brick, many of the windows are unglazed, and the lower story is used for warehouses, shops, and stables. The streets are but partially paved. The three divisions of the town are connected by two bridges, and it contains about 25,000 inhabitants. At the distance of a league stands Olinda on its hilly situation. It has about 4000 inhabitants, many churches, and public buildings; but it has lately been greatly deserted for the Recefe, which, from the excellence of the harbour, attracts all engaged in commerce. St Luiz, in the island of Maranham, capital of that state, is a bishop's see, and the residence of the captain-general. It is built in a straggling manner, containing squares and broad streets. The houses are neatly built; the ground floor is appropriated to various uses; the family occupy the upper story, the windows of which reach down to the floor, with balconies in front. The churches are numerous, and the inhabitants are about 12,000. Belem, the capital of the province of Para, is a regularly built and tolerably fortified town, almost under the line, at the confluence of the Tocantin and the Amazons. Besides these, Paraiba, Scara, Natal, Alcantara, Goiana, Rio Grande, St Christopher, St Paul, Villa Rica, and Villa Bella, are considerable towns.

Agriculture.—Dry situations, of a deep red soil, interspered with yellow veins, are chosen for the culture of cotton. The spot selected for a plantation is cleared of wood, holes are dug for the seed six feet asunder, into which it is deposited immediately after the fall of the first rain. The cotton is a precarious crop, and often fails. Between the rows of cotton, maize is generally planted. The sugar plantations occupy the moister districts, on which a good deal of tobacco is likewise cultivated, the seed of which, previously to its being sown, is mixed with wood ashes, to prevent it from being eaten by the ants. The manioc, or cassada, which is here the staff of life, is planted in beds on good soil; the roots of this valuable plant degenerate if the soil is not frequently changed. The banks of the rivers are well adapted for the culture of rice, considerable quantities of which are raised, especially in the province of Maranham. Wheat is also cultivated in the southern districts. The cocoa-nut tree, applicable to so many useful purposes, is planted on sandy soils, ten yards asunder, and requires no other care except to be kept clear from brushwood till the plants have attained a certain age. The agriculture of this fine region is still in its infancy.

Gold and diamonds.—Much gold and many diamonds have been, and are still found in the cavities and water-courses of the mountains, in conglomerated rocks and deep ravines, and still more frequently in the banks and beds of the rivers. Jaragua has long been famous for its gold. When water can be commanded, the ground impregnated with the metal is cut into long steps, below which a trench two feet deep is dug. As the water flows over these steps from above, the negroes work the earth into a mud, and in this state it flows into the trench, and the heavy matter containing the gold falls to the bottom. It continues in this state for five days, when it is carried to the next convenient stream to undergo a second clearance. For this purpose, funnel-shaped bowls are provided; the workmen, standing in the stream, fill their bowls with the sediment, which they mix with water, and move about so dexterously that the gold contained in the mass separates, and settles on the bottom and the sides. When this is effected, they rinse them in a large vessel of clean water, and begin again. Sometimes troughs are formed by laying planks on an inclined plane, in which hides with the hairy side outwards are laid, and over them water mixed with iron ore and particles of gold is made to flow. The gold is entangled in the hair, and to separate it the hides are taken out and beaten over a tank of water, and then replaced. After this operation, the sediment of the tank is treated in the bowls in the manner already described. At a convenient time after the gold is dried, it is carried to the transmutation-office, where it is weighed, and a fifth reserved for the crown. The remainder is smelted by fusion with muriate of mercury, cast into ingots, assayed, and stamped according to its intrinsic value, a certificate of which is given with it. After a copy of that instrument has been duly entered at the mint-office, the ingots circulate as specie.

Diamonds, like the gold, have been found at various places. At present they are sought for chiefly on the *Jigitonhonha*, a river equal to that of the Thames at Windsor. In the dry season the stream is turned into a canal, the *casalhão*, or earth which contains the diamonds, is dug up and carried to a place convenient for washing it during the rainy months. For this purpose, a shed thirty yards in length and fifteen in breadth is raised on posts, and thatched with long grass, down the area of which a stream of water is conveyed. On either side of this stream the floor is formed into troughs by planks laid on their edge, into which water is admitted from the canal. The negroes, in sight of their overseers, rake a quantity of the diamond-impregnated clay into the troughs, and there keep it in motion till the water runs clear, when the gravelly matter which remains behind is carefully examined for diamonds. When any are found, they are deposited into a bowl suspended from the roof of the shed. At the end of the work they are weighed and registered. The negroe who has the good fortune to find a diamond of $7\frac{1}{2}$ carats obtains his freedom, and is otherwise highly honoured. This branch of produce is entirely monopolized by the crown.

Commerce.—Cotton, sugar, hides, dye-woods, drugs, gold, and diamonds, are the principal commodities exported from the ports of Brasil. The trade to the coast of Africa is considerable. Some ships are sent annually to Goa. The demand for British manufactures is, it is said, daily increasing; and from the port of Pernambuco alone a hundred thousand bags of cotton go annually to England. The trade with the interior is carried on chiefly by itinerant merchants, who take cattle and other produce in exchange for their goods.

Government.—Brasil is divided into nine captaincies-general, besides several districts which belong to particular noblemen. Rio Janeiro, Bahia, Pernambuco, and Belem, are by far the most important of these provinces. To each of these, and the other divisions, a *captain* or governor-general is appointed for three years; on the expiry of which, at the option of the supreme government, he may be continued three years longer in office. The captain is commander in chief of the military force, and in other respects his power is absolute; but, before he can enter on the functions of his office, he is obliged to present his credentials to the *Sendo da Camara*, or chamber of municipality of the principal town of the district. The Ovidor or Juiz de Fora, judges of civil and criminal causes, are also appointed to each captaincy for three years, and may be re-elected.

From their tribunal there is no appeal, but they themselves may refer to a higher power. The Procurator, or attorney-general; the Intendenta da marinha, or port-admiral; the Escrivam da fazenda real, or chief of the treasury; and the Juiz alfandega, or comptroller of the customs, form the junta or council of the captaincy over which they preside.

Revenue.—When Brasil was first colonized, the clergy chose to receive a stipend in money in place of tithes, which, in consequence, became the property of the crown. Hence, a tithe of this kind is extracted from every species of produce; but, besides this, most commodities are subject to an additional impost. The tithe of cattle is levied, and then meat in the shambles pays a duty of about twenty-five per cent; fish is subject to the tenth, and afterwards to a fifteenth; cotton, after having paid the tenth, pays, on exportation, another duty of more than a penny per pound; rum pays about a fourth of its value in taxes; and imported goods are subject to a custom-house duty of about fifteen per cent. These heavy taxes are farmed by the highest bidder,—a circumstance which, together with their own exorbitance, and the existence of crown monopolies, tends to oppress the people, to relax the spirit of industry, to blunt moral sentiment, and to open the sources of every kind of crime.

Army.—The regular army of Brasil is said to be composed of men of every cast, colour, and character, to be but poorly paid, and wretchedly clothed and disciplined. Every man, however, from the age of sixteen to sixty, serves in a military capacity, either in the militia or in the ordenanças. Each township has a regiment of militia, which, with the exception of a few of the officers, serves without pay, and which is obliged to assemble yearly in uniform. The ordenanças are a kind of local militia, which neither receive pay nor wear uniform. The Capitam mor, the captain-major who commands a district, makes an occasional circuit through it for the purpose of reviewing his men, which he does sitting at his ease within doors at a table. He is attended by the captain of a company who calls the catalogue of his men, and each, as he is named, approaches, presents arms, turns, and retires.

The removal of the Court of Portugal to Brasil.—This extensive territory was in the year 1500 taken possession of for the crown of Portugal by Pedro Alvarez Cabral, who discovered it on a voyage to the East Indies. After it had been colonized, its possession was long and obstinately disputed by the Dutch; and had Maurice, count of Nassau, been enabled by his country to accomplish his comprehensive and judicious plans for conquering and securing it, Brasil at this day might have belonged to the Dutch; but a narrower policy prevailed, and the Portuguese recovered the ascendency, and ultimately the undisputed sovereignty, which they still retain. In 1806, while Bonaparte was carrying death and destruction into many of the kingdoms of Europe, the royal family of Portugal emigrated, under the protection of Sir Sidney Smith, to their dominions in America, where they arrived early in 1807; and ever since that period Rio Janeiro has been the seat of the Portuguese government. Within these few months the province of Pernambuco has discovered a disposition to revolt from its allegiance to the house of Braganza; but, from the latest intelligence which has reached this country, it would appear that the spirit of resistance will soon be quelled. See Mawe and Koster's Travels, and Southey's History of Brasil.

BRASIL WOOD, or BRASILETTO, a dye-stuff obtained from the *Cæsalpinia Brasiletto Lin*, a native of the American continent. See BOTANY and DYEING.

BRASS, a metallic alloy, composed of copper and zinc. See CHEMISTRY.

BRASS, CORINTHIAN, an alloy of gold, silver, and copper, which was famous in antiquity, and is said to have derived its origin from the disastrous conflagration which followed the plunder of Corinth by Lucius Mummius, nearly a century and a half before the Christian era. The vessels and implements of gold, silver, and copper, with which that celebrated city abounded, being melted by the fire, produced the compound to which it gave its name.

BRASSICA, a genus of plants belonging to the class Tetradynamia, and including under it many important species, as the turnip, cabbage, and their numerous varieties. See GARDENING.

BRAVO, or BRAVA, one of the Cape de Verd islands on the western coast of Africa; lies in 15° of north latitude, and is more than 400 miles distant from the nearest point. It is not more than four leagues in circumference, and the surface is chiefly composed of elevated land rising into mountainous peaks; but the soil of the intervening vallies is rich and fertile, and produces Indian corn, gourds, water-melons, and potatoes. Oranges and lemons are abundant; the vine, which affords a wine not inferior to Canary, thrives well; the culture of cotton is in some degree attended to; and the rearing of horses, asses, cows, and hogs, is not neglected. The commercial intercourse of this island is chiefly limited to the supplying of ships navigating the Atlantic with refreshments. For this purpose some of its bays and roadsteads are commodious and safe during the spring season.

BRAVA, a small independent state lying between the coasts of Zanguebar and Ajan, and tributary to the Portuguese. The chief town is situated on a bay at the mouth of a river, about 90 miles S. W. from Magadoxa, is well built, and strongly fortified, and in the early period of its history enjoyed great commercial prosperity. The trade in gold dust, silk, and cotton stuffs, ivory, and different kinds of drugs, it still considerable.

BREAD is a very general name for some farinaceous matter formed into a paste with water, and prepared by means of heat for the purpose of food. With this view, various substances have been employed; but the use of grain, or the seeds of those vegetables which come under the denomination of *Cerealia*, is by far the most extensive in all nations which have arrived at any degree of civilization.

History.—The invention of the art of making bread has been vainly sought for among the nations of antiquity. Regarding it as a discovery highly beneficial to mankind, the Greeks, in their fondness for fable, or under the grateful impression of its importance,

Bread.

ascribed it to a direct communication of their gods. But this art, as well as every other which commences with rude beginnings, cannot date its origin, in a state of great perfection, from any precise period. The perfection of almost every art is the result of slow and successive improvements, many of which are oftner the consequences of fortunate accident, rather than the effects of studied research or laboured invention.

It appears from the history of the Jews, that leavened bread was known to that people in the time of Moses; for among the precepts delivered for the regulation of the feast of the passover, the use of leavened bread was prohibited during that festival. The art of making bread was early known among other eastern nations; and indeed it may be fairly presumed, that the inhabitants of those countries which abound in corn, as they advanced in civilization, would be assiduous in devising various modes of preparing it as food which would render it more agreeable to the taste, and of easier digestion. In Egypt, Chaldea, and Greece, countries whose rich soil and favourable climate furnished the best materials, the art of making bread reached a high degree of perfection. The Romans, who were indebted to the Greeks for their improvements in science as well as in many of the arts of life, derived their knowledge of the method of making bread from the same people, and, indeed, the trade was long practised by natives of Greece. When the Roman armies returned from Macedonia, about 200 years before the Christian era, they were accompanied by a colony of Grecian bakers, who settled in Italy; and of 329 public bake-houses which existed in Rome in the time of Augustus, almost the whole number was occupied by Greeks. Many regulations were made for the government of that class of tradesmen, and many privileges were conferred upon them; thus affording ample evidence of what importance their services in the community were regarded.

Different kinds of bread.—The Romans had different kinds of bread. The finest kind was made of the best flour, and from a particular species of wheat which grew in Campania; the next kind, called second bread, retained a portion of the bran; the third kind was made of the whole substance of the wheat; and the fourth kind, called bran-bread, was chiefly composed of bran, and of a very coarse quality. Beside these kinds, the bread prepared by the soldiers, denominated military bread; the bread called the bread of the citizens was distributed to the people in the latter periods of the empire; sea-bread, corresponding to the sea-biscuit of modern times; bread baked in an oven, or on the embers; sour bread; unleavened bread, and other varieties, are mentioned in Roman history.

In religious houses four different kinds of bread are spoken of; the first called esquires' bread, the second monks' bread, the third boys' bread, and the fourth servants' bread. A similar distribution of the different kinds of bread seems to have been established in the household of nobles and princes. The French are celebrated for the excellence and variety of their bread; but in this country, in reference to loaf-bread of the flour of wheat, three kinds only are recognised.

Bread.

Ingredients.—The materials of which bread is made, it has been already observed, are chiefly farinaceous grains; but the ingredients which enter into the composition of the grain of wheat, only answer the purpose of affording loaf-bread of a good quality. The constituent parts of wheat, as they have been ascertained by Mr Edlin, are three ounces of bran, ten ounces of starch, six drachms of gluten, and two drachms of sugar, from a pound or sixteen ounces of wheat. From this analysis, it appears that the starch is in the largest proportion; but it is on the sugar, though in small proportion, that the peculiar fermentation, which is necessary for bread, depends; and no substance can be converted into good bread without a certain portion of gluten.

Nature of the process.—When wheat flour is to be converted into bread, it is formed into a paste with water, the proportions of which vary according to the age and quality of the flour; a quantity of leaven is added to the mass, to promote the fermentation; the yeast, or frothy matter, which rises to the surface of fermenting beer, is also employed for the same purpose. But the baker may prepare for himself, in the course of 12 or 14 hours, his own yeast, by adding one gallon of boiling water to about five pounds of flour, stirring the mixture well into a paste, and adding, at the end of seven hours, about a pint of yeast. The mixture being kept in a warm place for six or eight hours, will pass through the process of fermentation, and be ready for use; and the quantity thus produced will yield sufficient leaven for 50 or 60 quartern loaves. The exact quantity of leaven necessary for the proper fermentation of the paste or dough requires some attention; for when it is deficient in quantity the process is interrupted, and the bread thus prepared is solid and heavy; and if too much leaven be employed it communicates to the bread a disagreeable sour taste. When the fermentation succeeds properly, the paste swells up, and is greatly enlarged in bulk; this change is owing to the formation of carbonic acid gas, which is produced during the process, and is prevented from escaping by the viscidity of the glutinous part of the flour. To this fermentation the name of *panary* has been given, on the supposition that it has some peculiarity which distinguishes it from the vinous and acetous fermentation; but the only difference probably arises from the consistence of the ingredients. The vinous fermentation arising from the decomposition of the saccharine matter of the flour, is the first change which takes place in the process; and if this be allowed to proceed, the acetous fermentation commences, and some of the other ingredients of the flour are also decomposed. When the dough has undergone a proper degree of fermentation, it is divided and formed into loaves, and introduced into an oven previously heated. The temperature is usually regulated by throwing a little flour on the bottom of the oven. If the flour become black without taking fire, the oven is supposed to have acquired the proper degree of heat; and this is found to be 448° Fahren.

M. Duportal of Montpellier, who has paid consi-

Bread.

derable attention to the fermentation of bread, proposes a theory somewhat different. The ferment, he observes, having converted the saccharine portion of the farinaceous matter into carbonic acid gas, and into alcohol, changes this into acetic acid. The gluten and the albumen are partially decomposed, acetic acid is again produced, some ammonia, and more carbonic acid; and the starch combining with the undecomposed gluten, forms a compound, the farther change of which is prevented by the action of the fire, which produces a more intimate combination of these constituents."

Kinds of bread in Britain.--Three kinds of bread are made in this country, according to the regulations of the legislature, which requires that they shall be marked with the initials of the names by which they are distinguished. Thus, the wheaten loaf, which is made of the finest flour, is marked with the letter W.; the standard wheaten, which is made of the whole flour mixed together, is marked with the letters S. W.; and the household bread, which is made of the coarser flour, is marked with the letter H. The loaves are generally divided into peck, half-peck, and quartern loaves, and the following are the weights, Avoirdupois, of each, before and after baking; but it must be observed, that the weight, after baking, is required by the law to be examined within 48 hours.

	Before Baking.		After Baking.		
	lb.	*oz.*	*lb.*	*oz.*	*dr.*
Peck-loaf -	19	12	17	6	0
Half-peck -	9	14	8	11	0
Quartern -	4	15	4	5	8

Method in London.—If a sack of flour, consisting of 5 bush. and weighing 280lbs. is to be made into bread, the following is said to be the process generally followed by the London bakers. The flour is first sifted through a fine wire sieve into the kneading trough, not only for the purpose of separating the impurities, but also of making it lie loosely and lightly in the mass; four pounds and a half of salt are dissolved with a pailful of hot-water in a tub; and to this solution an ounce of alum, previously dissolved in a separate quantity of water, is added. In some cases, it is asserted, when the flour is of an indifferent quality, the saline ingredients employed are composed of two pounds and a quarter of common salt and an equal quantity of alum; to this mixture, when it is reduced to a temperature between 80° and 90° of Fahren. three English pints of yeast are added, the whole is well mixed, strained through a sieve, and poured into a cavity made in the flour in the kneading trough, and being well incorporated with it, is brought to the state of paste or dough. A little dry flour is spread over the surface; to retain the heat it is covered with cloths; and in about three hours, by the action of fermentation, the mass enlarges in bulk. Another pailful of warm water is added and well mixed with the dough, which is again covered up and allowed to remain for four or five hours, at the end of which time it is kneaded for more than an hour, with the addition of three pailfuls of warm water. The dough is then divided into pieces, returned to the trough, sprinkled with a little dry flour, and at the end of about four hours again kneaded for about half an hour; and being divided into pieces of the requisite weight for the kind of loaf intended, is moulded into the proper form, and introduced into the oven, where it is baked for about two hours and a half.

Use of alum.—Of the use of alum in making bread much speculation has been indulged, and it is probable a good deal of misrepresentation has been employed. It is scarcely to be expected that correct information is to be obtained by the officious and suspected enquiries of chemists; and their experiments are in many respects liable to erroneous results. The London bakers are roundly charged with the invariable practice of using alum in a certain proportion for the purpose of rendering the bread whiter and improving its appearance, and in some cases, as is noticed above, the quantity employed is enormous; but the use of alum, it is said, is not universal. On the same loose authority it is asserted that bread of the very best quality is made without it. It must appear not a little singular, that the bread of London, where the best wheat is to be had, where the finest flour is manufactured, and the art of baking has been longest practised, should be of an inferior quality, as some assert, and worse than most of the bread in Great Britain.

Proportion of water.—The proportion of flour and water varies according to the quality of the flour. The best flour absorbs the largest quantity of water; in some cases the flour combines with three-fourths of its weight of water; but in others with not more than half its weight. This affords a simple test for ascertaining the quality of the flour. When bread is made of flour of the best quality, it retains nearly one half of the water employed in forming the dough; but deviations take place, as well from the previous management, the regulation of the temperature of the oven, and some other circumstances, as from the quality of the flour.

Use of salt and yeast.—The addition of salt renders the dough capable of combining with more water, increases the quantity, corrects some of the bad qualities of the flour, and makes the bread fit for keeping longer. The use of yeast as a substitute for common leaven, is regarded as one of the most essential improvements in making bread; for it is found, that dough, to which yeast is added, rises sooner and better, produces bread of a lighter quality and less liable to a sour and disagreeable taste.

Household bread.—The following method of making household bread, is described as the practice followed in this country: Three quarts of water, with a handful of salt, and a pint of yeast, are added to one peck of flour; the whole is well kneaded together in a trough, and allowed to remain for about an hour, and when it has risen sufficiently it is divided into masses of the proper weight, moulded into loaves of the requisite form, and baked in the usual way.

French bread.---With the addition of some other ingredients, what is called French bread is made. To half a bushel of fine flour, ten eggs, a pound and a half of fresh butter, and an equal quantity of yeast are added. The whole mass is mixed up and kneaded with new milk, pretty hot; and having been left for sometime to rise, is divided into loaves or rolls,

Bread.

which are washed over with an egg, beaten up with milk, and then baked, with the precaution that the temperature of the oven be properly regulated, and particularly that it be not too high.

Rye-bread.---Rye is used as bread very extensively in some of the northern countries of Europe; its use is also not unknown in the form of loaves in the north of England, and in some parts of Scotland. Bread from the flour of rye is of a brownish colour, and the taste is sweeter than the bread of flour from wheat. From the analysis of rye, it appears that the quantity of saccharine matter, on which the fermentation depends, is sufficient for that process; but the proportion of gluten is small, and hence it happens that, when rye-flour alone is used, the bread is compact and heavy; with the addition of a portion of wheaten flour, a light, well-tasted, and nutritious bread may be made of rye.

Rice Bread.---Rice appears to contain in its composition a large proportion of starch. Various methods have been tried and recommended for making it into bread. A quantity of the flour of rice is mixed with a portion of water, which has been boiled with a few handfuls of rice in grain till the liquid becomes viscid; and, with the addition of the proper proportion of salt and leaven, the whole is kneaded together, and the dough is covered up for some time till it rise. During the fermentation the dough assumes a liquid form, which renders it unfit for being wrought by the hand. In place of this operation, it is introduced into a tin-box, with a little water, covered with a leaf of paper; and the box being put into the oven, previously heated, and dexterously inverted, by the sudden action of the heat the dough retains the form of the box, and when baked affords an excellent bread.

The following process for making rice-bread is practised in America: The grain when well washed by repeated stirring and affusion of water, is drained and beaten in a damp state in a mortar to a fine powder, which being thoroughly dried is passed through a hair-sieve and mixed with a small proportion of Indian corn-meal or with boiled potatoes. A proper quantity of salt and leaven is added to the mass, and, after undergoing a sufficient degree of fermentation, is put into pans and baked.

Potatoe-bread.---In numerous experiments instituted by M. Parmentier, a French chemist, excellent bread was made from various proportions of meal from potatoes and wheaten flour. Bread of the meal of potatoes alone was apt to crumble; to render it adhesive, he added to the meal a decoction of bran, or a mixture of honey and water. He obtained also a well-fermented, agreeably tasted, and light bread, from a mixture of raw potatoe-pulp, with the flour of wheat or of potatoes, and with the usual proportion of yeast and salt. Equal quantities of wheaten flour and potatoe-meal were found to answer extremely well. The same chemist produced bread which approached nearly to that from wheaten flour, from a mixture of four ounces of potatoe-starch, one drachm of the mucilage of barley, one drachm of the bran of rye, and a drachm and a half of glutinous matter dried and reduced to powder.

Another method of making potatoe bread, is to put a quantity of potatoes, well boiled and peeled, into a trough, to cover them with boiling water, and to reduce the whole to a uniform consistence into the form of a soup. A certain quantity of this mixture, as a half, a third, or a fourth, is kneaded with wheaten flour, and, after being treated in the usual way, affords a bread of an agreeable taste, and of a very nutritious quality.

Turnip-bread.---A palatable bread, it is said, has been made of turnips mixed with a certain proportion of wheaten flour; and as it may be useful in times of scarcity, the following method of preparation has been recommended. The turnips being pared, boiled, and mashed, and the greater part of the water being pressed out, an equal weight of coarse wheat-flour was added. The dough was prepared in the usual way, with yeast, salt, and water, rose well in the trough, and, after being kneaded, was formed into loaves, and baked. It was allowed to remain in the oven rather longer than other bread. The turnip-bread thus prepared was white, light, and of a sweet taste, but had something of the flavour of the turnip, which in the course of twelve hours was scarcely perceptible. At the end of twenty-four hours no indication of the taste of turnips could be detected; and after being kept a week it was found to be as good as ordinary bread.
